Address

THE SUNSHINE AND SHADOW IN MEDICAL ENDEAVOR.*

JOSEPH D. BRYANT, M.D.

NEW YORK CITY.

Justice to myself, and a proper consideration for those whose faith or curiosity has prompted them to be present on this occasion, impels me to say at the outset, that I have been not a little troubled to select a topic that might suitably meet expectations and at the same time afford an excuse for my presence. I might, perhaps, *with a faint trace of propriety, lighten each* of these contingencies with the guileless claim that neither you nor I can be regarded entirely responsible for a crisis which has been *fostered for a considerable time*, and is now launched by those who are charged with the success of the occasion. However this may be, a reasonable fidelity to those who have so implicitly trusted us, should beget praiseworthy patience in you, and a degree of commendable brevity in me that befits your present comfort and the character of the topic *under consideration*.

The theme of the evening as already announced is somewhat euphonious, but quite suited, as it seemed to me, for an occasion of this kind; one healthful in all respects, *dignified by character and learning, and* adorned by beauty and grace.

In order that there may be no suspicion in the minds of any, that the *topic of our choice is intentionally* clothed in a garb of mysticism, I hasten at once to say that the *expression, "The Sunshine and Shadow"* has no hidden meaning, but is chiefly employed on this occasion to express in a metaphoric and more agreeable, but in no less *emphatic way, the well recognized results* of our profession, in the long struggle for the relief of human affliction. The glorious sunshine of medical achievements is reflected in the happy faces and glad manners of the patients and their friends, also in the gratified expression of the otherwise imperturbable demeanor of the experienced *medical attendants*.

Bereft, indeed, of healthy human sentiment are those whose hearts are not gladdened by the melodious expression, "the patient is better," "is out of danger," "is well again," *thus indicating to all concerned that* nature's forces, aided by those of genuine medical endeavor, have [illegible] yet another sufferer, thereby restoring happiness and help to loved and needy ones.

To those who thi[illegible] than their friends, and sympathize with them in their distress and forebodings, those *who have in their bosoms* thoughts of the welfare of mankind, the sunshine in medical endeavor *is seen in the results of the efforts of rescue of all men, of all climes, from physical distress,* thus adding correspondingly to the comfort and prosperity of the whole people. No financier notes with *greater care* the fluctuations in monetary affairs, nor accounts for the *variations more astutely, nor appreciates more keenly the import of the changes, than does the true physician* note and estimate the varying results of genuine medical endeavor, in the different medical centers, and in *the medical clearing houses of the civilized world. The* features of the former brighten with the gratifying sensation of the knowledge that he is the possessor of greater *wealth, and let us hope of greater determination to* aid the unfortunate and to add to the world's enhancement. The features of the latter are brightened by the sunshine of the facts, that the beneficent endeavors of his profession have robbed pain of its terrors by means of the strengthening slumber of anesthesia; have stripped infection of its dread by the power of sani*tation and asepsis, and have disarmed fata*[illegible] and distressing disfigurement by means of s[illegible]cination.

These achievements alone have added more treasure and comfort to the world than a[illegible] quests have destroyed since their time; they h[illegible] *more to a nation's financial and human assets,* [illegible] all of its victories. The bounteous achievem[illegible] physician are attained in comparative siler[illegible] unobtrusive effort as becomes his [illegible] therefore much less manifest and unde[illegible] ple than are *the achievements of statesmen* and w[illegible] riors, whose general aims and activities are only *rarely* out of sight and hearing, and whose final rewards emphasize in no uncertain *manner the confidence and* appreciation of the people. The sunshine of success*ful effort and* of appreciative response gladdens the heart of the true physician no less than it does the heart of one who achieves *beneficent triumphs* in other fields of action.

Those who guard the security of individual existence in the cool moments of every day life exhibit quite as *great and often greater steadfast bravery than do those* whose fortitude is strengthened and whose efforts are stimulated by the fascinating din and *intoxicating allurements of battle. But enough of this feature of the* matter has been said, for were I to continue longer in this manner of expression you might be led to believe that I am partial in my views and utterances regarding *the achievements and the burdens of those of my own* profession.

As you will no doubt recall, my theme provides for *shadows as well as sunshine in medical endeavor*. The shadows in medical endeavor, like other shadows, bespeak the absence of enlivening sunshine, and *suggest* the want of the good cheer that accompanies the need of its presence, more especially in the counterfeit form of endeavor. Sunshine and shadow have antithetic attributes and attend on each other with a degree of fidelity that puts to shame the fealty of human co-operative action in tangible matters. Sentimental writers have noted this fact and utilized it in a delicious manner, as did Bovee when he sang, "False friends are like shadows, keeping close to us while we walk in the sunshine, but leaving us the instant we cross into the shade." Physicians have ample chance to mark the change from sunshine to shadow as modified by the acts and sayings of those dwarfed by the characteristics of complacency or envy. The gratifying sunshine of a conscientious physician's success is too often darkened by the distressing shadow of envy of those who find it easier to gaze into the large than into the small end of the glasses, and quite as natural, and then contend that small things and those beyond their conception or reach are too unimportant for serious thought, instead of keeping step with the comprehensive endeavor that leads the way in meritorious advance. Such persons as these clog the channels of success and are as brigands in the paths of enlightenment.

---

* A popular address delivered at the meeting of the Indiana State Medical Society, 1905.

The sunshine and shadow in medical endeavor! Again the topic is repeated, so that we may better emphasize the fact that the endeavor which we are considering is no less surgical than medical. Medical endeavor includes that of surgical, since the resources of the latter are as much remedial measures of cure as are other means of relief. The proper practice of surgery is based on experience and knowledge and on hard knocks, no less than is the practice of medicine.

I wish, with the requisite degree of emphasis for the
pu register my unqualified objections and stren-
tion to the idea, wherever it may be enter-
, the surgeon is the executive agent of the
nless, unworthily, he himself so chooses to
the judgment and services of the surgeon
cessary until the physician in charge sug-
they be secured, and perhaps because of a
omplication that requires for its interpre-
y surgical experience and surgical the-
is, I am happy to say, rapidly dis-
ing, not only because of the recognized fatality that too often follows late consultations, but because of the mutual appreciation of the greater services to the patient and to the profession of prompt and early co-operative thought and action. It would be strange, indeed, at this particular time, and would be reasonably dependent on heedless thought or unpardonable vanity on my part, were I not to insist with equal emphasis on the need of co-operative action in surgical instances as well as in medical.

The shadows of popular distrust and disapproval, and those of professional displeasure and censure, sometimes appear so suddenly and become of such magnitude as to smother by their unforgiving and spiteful character all efforts of explanation in instances of fancied or real oversight, referable especially to the treatment of distinguished public personages. So frequent and inconsiderate are those manifestations in such instances that "the head that wears a crown" can not lie more uneasily than that of one of our profession who is charged with the physical welfare of a person of markedly distinguished rank. Especially is this true when, in moments of misguided confidence or of mistaken policy, matters whose importance can only be properly estimated by the family of the patient or by the medical attendants, are given public notice. Aspiring and proud souls whose ambitions prompt them to place their names highest on the rugged face of an unconquered precipice are not more foolhardy in many instances than are those of our profession who affix their names to a public bulletin bearing details that offer the opportunity for invidious chatter of envious and self-constituted critics. The soothsayer who bade Cæsar "Beware the ides of March," were he living to-day, might with equal pretension bid us beware the "ides" and ends of medical bulletins of prolific recital.

Fearing that you may suspect that I, for some reason, yet feel the smart of the public lash, I beg to inform you that I am not "a bruised reed" that has been broken, nor have I been subjected at all to the Shakespearan form of chastisement as verbally dispensed by Cleopatra; therefore no one has said, like her, "Thou shalt be whipped with wire, stew'd in brine, smarting in lingering pickle," but medical friends of mine and of yours have been thus figuratively whipped by the mischievous and overwise utterances of those to whom have been graciously given or wisely denied, facts that can be properly construed by only those at the bedside of the patient.

In a lesser degree than in the preceding examples many of us occasionally receive more than we deserve, because of expressions that thoughtlessly escape us entering at once the public ear, or entering a private ear with public predilections. Let us then cultivate the sunshine of endeavor in these respects with a due consideration for the shadows begotten in our paths by the unwise or thoughtless indulgence of others in matters beyond their willing understanding.

It is the medical endeavor of modern age that has just engrossed our attention, the sunshine and shadow of which in all of their characteristics have been the natural product of the spirit of the times, as, in essential respects, no doubt, have been the sunshine and shadow in the medical endeavor of the early history of the healing art.

The knowledge and ability of healing the afflicted is developed in accordance with the opportunity and desire to cultivate the calling; the opportunity and the desire result from the willingness to seek relief and the degree of the devotion exercised by those who aim to provide it; the willingness to seek relief is prompted by the confidence reposed by the afflicted in those whose capacity for good is measured by the honest outcome of intelligent assiduity, exercised in a proper and adequate field for the purpose.

The laity too frequently clothe those of our calling, more especially the surgeons, with romantic attire, and often seem more impressed with the agents of our craft and by our utterances than by our material presence. They watch for something startling and even measure our importance by the magnitude of the exhibit; and not all of us, I am disposed to remark make perilous efforts to dispel the illusion. I now recall a physician whose appearance and manner were, to my then youthful and unsophisticated mind, the onification of Ajax defying the lightning. One day e presence of many by-standers, this physician was asked by a patient: "How much shall I pay you for your advice, doctor?" The pseudo-Ajax, rising to the occasion and to his full height at the same time, in a loud, convincing tone replied: "An ordinary doctor would charge you two dollars. I am an extraordinary doctor and I won't charge you but two." The interest of the onlookers seemed to me to increase a hundred fold at once, and so far as I am concerned, I am not quite willing to deny that a microbe of some form of ambition did not infect me at that time. Certainly every one present on that occasion seemed to be delighted to have been a factor in so startling an announcement, and the poor patient himself parted with his hard earned money, emitting a radiant expression of wonder and satisfaction that seemed to say, "By Jupiter, an angel, or if not, an earthly paragon," and at the same time unconsciously illustrating by his appearance the sentiment of Emerson, uttered perhaps twenty-five years before: "There is a remedy for every wrong and a satisfaction for every soul!" In this instance, however, the charge made was twice the sum usually asked at that time and place for the services rendered, and which on this occasion were for the relief of an illusionary complaint. It has been many years since this incident happened but not so many since similar ones have occurred. The circumstance then illustrated and still illustrates the subtle and controlling influence exercised on the minds of those with imaginative ills, annoying to themselves and friends and perplexing to the medical attendant, of the assertive declarations made by noisy and irresponsible persons.

Patients in despair because of these afflictions, encouraged by their friends and sometimes offended by the apathy or well meant sarcasm of the medical attendant, often reluctantly seek the relief offered by exploited means of cure. Sad it is that in these cases the medical attendant too frequently expresses his satisfaction for having thus escaped the irrational besetments of the victims of imaginary disorders. Such patients as these deserve abundant sympathy and are difficult to convince against their morbid inclinations and are cured only with great effort by ordinary officinal methods. On this unfortunate class of people the human buzzards prey with persistent eagerness and gratified glee, aided by the alluring statements and false beacons hoisted into view by selfish agents for the purpose of securing the gross gains of the soulless thrift encouraged by this form of business enterprise.

In secular, sectarian and medical publications are found too frequently alluring announcements of remedial promise, and the recital of cures that can have no foundation in real fact and which, it seems to us, should be well known to those intelligent persons who assume to educate us in all things relating to the flesh and to the spirit. If these misleading statements and their deplorable outcome be not comprehended by so distinguished and earnest public servants as are these same agents of enlightenment, whose efforts in the search of knowledge and truth in the affairs of men and nations, lead them to overcome all obstacles opposing the purpose, then indeed should the duties of the editor on "serious things" be so increased as to include an essay on the fact that "nothing is more terrible than active ignorance." I beg to suggest, as an earnest of the graphic utterance of Goethe, that the essay be illuminated with the shadows of the unfortunate, and the results of misguided hope as pictured by the emaciated forms and mental wrecks strewn along the pathway of delusive medication. If there be any of these who are not ignorant of the disaster which their business instincts invite, to them the least I will say is: Dismiss your family physician at once and administer to your children and take yourselves the curative agents you exploit, and in accordance with the directions on the package.

The worst that might be said to this class of persons is not fitted for utterance at this time and place, and in this presence.

I will, in this connection, give an illustration of the sentiment "Where more is meant than meets the ear." Perhaps, however, it is better to say, than meets the eye —as might have been said had the expression been written near to this period of frenzied enterprise.

Not very long ago a loyal friend of mine whose loyalty to me could only be measured by her loyalty to a certain sectarian journal from which she had gained in spiritual consolation and comfort for many years, chanced to call my attention to the "high character," as she expressed it, of the abundantly illustrated "business columns." I naturally wishing to take note of so important a fact, at once scanned the announcements relating to its business purposes and to other undertakings. It required no special scrutiny to determine the presence of several exploitations of things that fasten the attention of those of inquiring minds and confiding natures; those who, while waiting for something to turn up of substantial character, invest their unbounded faith and limpid assets in problematical ventures; those whose failing health from incurable or imaginary afflictions have often experienced "the sickening pangs of hope deferred," and ventured their all, with no other gain than this. However, I will mention only one, "A Cure for Consumption," at so much "per" bottle. I inquired of my friend why it is that in a publication of this character, devoted to spiritual matters and bearing a title that means Christian effort and Christian outcome that such an announcement as this appears on its pages. She frankly replied, "Because I assume that their presence here inspires greater confidence and is followed by larger returns than when announced by the secular press." I earnestly inquired, "Do you believe consumption can be cured by medicine alone, and do you not believe that such medication as is here announced is quite likely to be delusive and even destructive because of its artful composition and misleading effect?" She, being the wife of a physician, and therefore more interested and better informed in such matters than many others, promptly replied, "Yes, I do, and I will call on the editor and see about it, for surely he either believes the statement to be true, or is not aware of its presence in the publication." Later I saw the lady again and inquired if she had seen the editor and what he had said. "Yes," she replied, "I saw him and he said: 'I am not responsible for the advertisements, as the business affairs of the paper are no part of my duty.'" "Well," I inquired, with a somewhat confidential, continuously curved interrogative inflection, "what are you going to do now?" "I have written him already," she replied, "that unless that deceptive consumption cure is expunged, I will stop my subscription for the paper." I wish to say, in justice to the management of the publication, that after a little time the objectionable announcement ceased to appear, but for what reason I never knew.

While writing these lines it occurred to me to examine the pages of a number of sectarian publications periodically devoted to the enlightenment and the spiritual guidance of the people. Twelve different examples were selected without reference to any consideration [illegible] than the main object in view—the ascertaining of the presence or absence in the paper of the alluring recitals to the unfortunate afflicted already mentioned. The pages of the great majority of these publications were above reproach. The pages of a small minority of them were a sad commentary on sincere religious pretension and honest business enterprise. On a page of one appeared a sensible article illustrative of the fact that "Where there is prayer there is peace." On another page of the same publication was conspicuously announced, "The curing of cancer without the use of the knife," followed by "If you are seeking a cure come here and you will get it." In another instance was noted a three-quarter page announcement in which a list of not less than forty diseased conditions appeared, along with the assurance that in any stage of any of those diseases "The results are so certain" that gladly an absolute guarantee will be sent to any inquiring patient. The exact meaning of this phraseology is somwhat dim and is open to diverse conjecture; but that the intent is obvious and the outcome is remunerative is told by the liberal area of the space devoted to the purposes of the announcement. Among the diseases in the list were croup and Bright's disease, piles and cancer, constipation and tuberculosis, dandruff and women's diseases, along with the alluring bait, "A fifty-cent bottle free."

We all are more or less familiar with, and gladly welcome the happy inspiration that conceived the idea of tasteless, of agreeable, and of sugar-coated medication, but are we familiar with and do we approve of medication that has for its vital inspiration the misguided faith begotten by sanctimonious business enterprise?

One other instance of this nature and I am through with examples of these special shadows. In a local paper of a town and not in the list of the regular advertisements, but in a conspicuous place in the reading matter and therefore of a conspicuous price, is announced "A new cure for cancer," fortified with a certificate from a far distant state of a man who had a cancer of the lip that "seemed incurable," and "is now perfectly well." This medical agent is also guaranteed to cure cuts and burns—price twenty-five cents. I do not contend that this compound if applied to cancer will cause local harm, but surely it will not effect a cure and probably as surely will contribute to final disaster by delay of proper means of treatment, and possibly will rob the patient of established methods of benefit while chasing the delusive phantoms of hope, incited by the agents of thoughtless or of mercenary gain. The columns of many of the lay journals of the country are disgustingly disfigured with a humiliating class of notices, notices that filch from the helpless and unsophisticated their hard earned and much needed money, giving in return but renewed disappointment and often final disaster.

This form of filching is supplemented, in some instances, by one of far lower degree, whose slimy bids for trade exact a tax on the most unfortunate of the unfortunate class that abides with us. Neither the sunshine of medical endeavor nor even that of Christian endeavor has as yet uprooted, nor more than lessened the presence in conspicuous places of the beguiling hand-bills of thesse audacious vipers. Surely the failure of the efforts in accomplishing so righteous a purpose casts a fixed and almost impenetrable shadow, demomative of the frailty of beneficent human endeavor matters in the correction of such insatiable evils. The remedy for these conditions lies in the development of such a degree of moral determination on the part of all as will secure the enactment of corrective legislation and the development of an abiding courage sufficient to cause enforcement of the legal commands. I am disposed to believe that the wise and emphatic utterances of President Cleveland regarding such matters on the occasion of the semi-centennial celebration of the New York Academy of Medicine in January, 1897, can well be quoted at this time as an earnest of the opinions of all thoughtful, considerate and patriotic citizens. He said:

> You have established a code of ethics which condemns charlatanism in all of its forms, and yet ignorant pretenders roam over the land offering to perform miracles, or are located in our towns and cities preying on the weakness of the sick and afflicted, while men and women are allowed to die without medical attendance, deluded with the hope that faith will save them in their last extremity. Within the limits of your professional power and influence you seek to restrain any approach to criminal malpractice, yet newspapers disgustingly, though covertly, advertise the way to such crimes and startle their readers with sensational tales of death and misery to which they are directly accessory. I need not suggest that such evils are allowed to exist by reason of the insufficiency of our laws or the laxity in their execution. I have intimated that for this condition you are not responsible in a professional sense; but are you sure that as citizens you are doing all in your power to remedy the situation?

The potency of these remarks is the product of the careful thought and acute observation of a distinguished citizen whose fearless loyalty to the public interests has frequently been demonstrated in no uncertain manner.

I am fittingly reminded at this time by the sacred lessons of the greatest of all teachers, that "He that is without sin let him first cast a stone." Also, "And why beholdest thou the mote that is in thy brother's eye, but perceivest not the beam that is in thine own eye? How canst thou say to thy brother, Brother, let me pull out the mote that is in thine eye, when thou thyself beholdest not the beam that is in thine own eye?" No one is more aware than am I of the number and the magnitude of the motes and the beams in the eyes of those who profit by the unethical policy of medical journalism. No one is more aware than am I that until quite recently, the casting of a stone in any direction of the compass exposed to justifiable hazard the metaphoric eye of an offending medical journal, and possibly of a noted practitioner. The failure to recognize the essential differences between thrifty commercialism and ethical proprieties has been a blighting reproach on the ethical pretensions of our profession, subjecting us to biting jests and humiliating scorn painful to bear and difficult to gainsay. But I am gratified to be able to announce that an apparent era of consistency in this respect is at hand, and is rapidly increasing in all directions, embracing alike the personnel and the press of our profession. Let us, therefore, congratulate ourselves for ourselves because the rising sunshine of professional consistency is now dispelling the gloomy shadows of professional inconsistency that have too long darkened the path of consistent medical thought and action.

The construction of even a very brief retrospective review of the birth and past attainments of our profession requires abundant leisure, infinite patience and unrestricted access to almost numberless records representative of all nations, and of all ages, in order correctly to understand the earliest periods of medicine and surgery and the sequence of their logical development. We can do no more on this occasion than to touch lightly here and there at long distances apart along the pathway of advance, thereby fitting us the better to appreciate the full significance of modern medical triumphs as demonstrated through the effulgent sunshine in medical endeavor. The beginning of medical thought and action is so obscure and so intimately associated with the strange conceits and fantastic beliefs of early recorded time as to make impossible the fixing of a period of commencement in established medical endeavor. Medical thought and action at that time were a part of the imaginative features of early human existence, when superstition and false philosophy dominated the actions and beliefs of men. In ancient times, the physician of a locality was its magician and conversely, as sometimes happens now in pagan and aboriginal countries. The art of healing was then regarded as most mysterious and its agents were believed to be in communion with spirits. Amulets were worn to chase away the ague, extracts from the Iliad to lessen the suffering of gout, and a verse from Lamentations for cure of rheumatism.

But do not, my friends, pity too soon these ignorant people, nor indicate by signs a doubt regarding their mental equilibrium, for neither you nor I know how many here this evening pin their faiths of cure or prevention of rheumatism to a well-worn horse chestnut deposited in the left-hand trousers pocket; nor how many experience relief from insoles made of mullen leaves; nor how many are benefited by brass rings worn on a special finger or toe, which ring extracts the virus of disease, as is asserted to be proved by the presence on the ring, from time to time, of the products of oxidation, and, pardon me if I suggest, of careless personal sanitation. Lessing truly said, "The superstition in which we were brought up never loses its power over us, even after we understand it."

An ordinary scrutiny of the advertising columns of the secular press to-day will furnish exhibitions of the perverse ingenuity of man, affording him ample subsistence because of the presence now of receptive beliefs like those of the earliest times.

The prescriptions of early times are a caution to modern pharmacy. Galen and Avicenna secured greater professional repute as successful physicians than is possible in our period, and, were their famous prescriptions to be given now, it seems quite certain that more patients would succumb than receive benefit from their use. Yet in their time these prescriptions were employed with seemingly marvelous success. Do these facts suggest an absence of stability of medication, or only the presence of its fallacies?

In the second edition of a small book published in 1692, denominated the "Choice of Remedies," is found this prescription for "Convulsive Fits" and "Hysterical Vapors:" "Take the liver of a hare (if it have been hunted it may be better) and hang it up in a dry place till it is somewhat friable, having a care that it is not putrific; of this reduced to powder let the patient take two or three scruples at a time, in any convenient vehicle." Also we find another for cure for cancer of the breast: "Take the warts that grow on the hinder legs of a horse, dry them gently till you can reduce them to powder, of which you may give half a dram for a dose in any convenient vehicle." This latter agent had the merit of doing no local harm, even though it could be of no special good.

In this connection, I am reminded of the fact that in my early youth a fond and solicitous domestic gave me freely of grated dried pumpkin stem and molasses for the cure of colic. Whether or not the sweetened sunshine of the molasses or the insipid shadow of the pumpkin stem or the implicit faith entertained in the curative virtue of the remedy or, perhaps, only old-fashioned homely coincidence afforded the relief in this instance of medical endeavor, I am not prepared to say.

On closer examination of this little book on "Choice of Remedies," one is forced to the conviction that, indeed, much sunshine should have followed medical endeavor when attended by the dark shadows of such sickening therapy, the proper vehicle for which I am disposed to say should be the ash cart of a modern city. It should not be overlooked, however, that they did then, as we do now, the very best they knew.

The recorded growth of surgery began 3,000 years ago, and the tangible evidences of surgical endeavor antedate this period an unknown length of time. Fossil examples of prehistoric trephining done some time during the polished stone age may be cited as examples of this fact. About 1,550 years before the birth of Christ was made the following record regarding a tumor: "If this tumor goes and comes under your finger, trembling even when your hand is still, say it is a fatty tumor and treat it with the knife, after which treat it as an open wound. A work on anatomy (a true foundation of safe surgical endeavor) was in existence about 5,240 years before the birth of Christ. The Old Testament contains expressions relating to medicine and surgery. And we find, at that time, an expression that has come down to us with a pungent flavor not greatly attenuated, though highly seasoned with the smart sarcasm of the day. King Asa, "In his disease sought not to the Lord, but to the physicians." And, "Asa slept with his Fathers!" In Exodus is found this statement: "And if men strive together and one smite another with a stone, . . . then shall he that smote him . . . pay for the loss of his time and shall cause him to be thoroughly healed." or, when practically rendered, shall pay the surgeon his fees.

About 1,000 years before Christ, Homer in his songs described the wounds of the conflicts of that period and the method of their treatment, which in some respects may be regarded as rational for the present time. In the fifth and sixth centuries before Christ, numerous temples erected to Æsculapius, the father of medicine, were extant, to which the afflicted resorted for relief, suggestive of the dispensaries of to-day. At these places, certain medical families, having presumptively special medical endowments, dwelt and treated the complaints of the callers, not in accordance with any established dogmas, but in accordance with their own individual conceptions of the means best suited for medical and surgical relief. It is likely that each individual family had its own records of remedies, of methods and of results, which were transmitted from father to son, just as one now finds in a good old-fashioned family "grandmother's recipe for cake" or for colic. And, also, perhaps, not unlike the self-constituted doctor of our day, who prescribed corn beef and cabbage for a blacksmith suffering with cramps, with instant relief, and so recorded the fact. Later, however, a minister thus afflicted called him in and was given the same treatment but promptly died. Whereof this unprejudiced rec[illegible] of facts made the following entry in his record of endeavors: "Corn beef and cabbage is good for a blacksmith with cramps, but ain't worth a d—n for cramps in a minister."

Hippocrates, the father of medicine, born 460 years before Christ, was the offspring of a direct family of medical practitioners. Prior to his time medicine and surgery were but little advanced, and a distinct line of demarcation had not been drawn between them. Dr. Hippocrates, like some doctors of divinity, had great faith in the efficiency of fire as a remedy. The maxim of Hippocrates that "the diseases which are not cured by medicine are cured by iron; those not cured by iron are cured by fire, and those not cured by fire are incurable," was the cause of great suffering and of bad surgery—and theology—up to nearly the present century. Hippocrates and his students were prolific writers on surgical topics. They wrote on injuries of the head, on fractures and dislocations and sympathetic fevers, and many of their statements are to-day a part of the structure of modern established surgery. Thus it appears that the wise men of that period were able to establish enduring truths in medicine and surgery of significant modern importance, and, too, without the aid of the special means of analysis that characterize the bountiful period in which we live.

It may not be amiss to observe in this connection that the powers of human reasoning in diagnostic attainments are developed in direct proportion to the paucity of other means than this of reaching final conclusions in the field of differential endeavor. Conversely, inductive diagnostic attainment, if not carefully fostered, will be disabled by the vigorous assaults made on reasoning effort by use of the novel expedients employed in diagnostic aims; not necessarily because of the abundance of expedients, nor of their presence, but because it is human to accomplish a perplexing desire with as little effort as possible. The scant danger that now attends "explorative incision" is apt to encourage a degree of mental contentment, inhibiting the reasoning powers, so as to be followed, after brief and unconvincing effort, by the expression, "Oh! well, an explorative incision will settle it."

Let us now turn to a more pleasing picture, illustrative of the sunshine and shadow in medical endeavor as demonstrated by the direct results of professional effort in the alleviation and cure of preventable human affliction, during many years of toil of those of our calling. It is well to be reminded here that of one million human beings born a hundred years ago only about three hundred are now living, and they are living but feebly, cheered by the recollections of the past.

In this connection, you should be told that, during the last hundred years, the expectation of life has been remarkably advanced. The ubiquitous "King of Shadows" has been moved many more paces to the rear of the "shining marks" that he so much loves to demolish. The expectation of life in New York City in 1886, says Dr. Biggs, was only a little more than twenty-five years, while in 1903 (17 years after) for the same period the expectancy had nearly doubled, equaling quite forty-one years, and constituting an equivalent in the saving of life in that city of 28,000 lives annually. In the seventeenth and eighteenth centuries, according to Dr. Biggs, the average death rate of the civilized world was about 50 per 1,000. In London, from 1628 to 1635 (in the absence of pestilence), the average death rate was 50 per coo, and the absolute mortality there for twenty-four mol 1620-1643) was over 70 per 1,000.
matters

So much for shadow in medical endeavor. Now mark the sunshine. In London, in 1902, the death rate was but a fraction over 17 per 1,000. In London, from 1771 to 1780, 5 per 1,000 died of smallpox; in 1880, 2 in 1,000; in 1837, 1 in 12,500; in recent years the death rate per 1,000 from smallpox in London is expressed by an insignificant decimal.

In 1888, in the Department of Health of New York City, the initiative in the present war against tuberculosis in this country was begun. Then and for some time following, the idea was regarded by distinguished members of the medical profession of the city as being meddlesome, puerile and demoralizing and doomed to prompt and inglorious defeat. At that time the medical commissioner of the Department of Health of that city addressed to each of twenty-five of the leading physicians of the city a letter inquiring if, in their opinion, the time had not come when tuberculosis should be regarded as a communicable disease and measures be taken to combat it, based on the reporting to the Department of Health by the medical profession of the cases of this disease coming under their care. From the great majority of the twenty-five thus addressed no reply whatever has yet been received. From the small minority halting replies of the "Yes, I guess not" type came to hand and to ear. But two only of the twenty-five responded promptly and in the affirmative. Physicians of lesser rank than those already mentioned amused themselves and others of high attainment and doubting method by means of cheap writings and sayings that prompted mirthful comments on the part of those with no faith and little desire to aid in the undertaking. Since that time (1888), however, the cause has made rapid progress, and physicians who then deprecated the attempt are now convinced of its wisdom and are using the weight of their eloquence and standing to secure sufficient monetary support from the city and from citizens to provide for the care and relief of the minority host of this class of sufferers. The rewards of effort thus far gained can be no better related than by Dr. H. M. Biggs, who has been among the foremost in aggressive action and suggestion of those who have engaged in the conflict against tuberculosis. Says Dr. Biggs:

> The average death rate in the Boroughs of Manhattan and the Bronx from all tuberculous diseases for the five-year period preceding 1888 was 4.35 per 1,000 of the population and for the five-year period preceding Jan. 1, 1905, was 2.83, the decrease exceeding 35 per cent.; or, going a little farther back, in 1881, the rate was 4.92, and twenty years later, in 1902, it was 2.63, or a decrease comprising only these two years of 45 per cent. Translated into lives, the difference in the rates for the five-year periods, computed on the present population of Greater New York, means a decrease in the annual deaths from tuberculous diseases of over 5,500 in the greater city.

Nor is this but a little, my friends, of what has been accomplished in life saving during the average age of those within this inclosure. Surgeons who labored in the hospital wards before the days of antisepsis and asepsis will recall the abundant harvest of lives and limbs gathered in by the almost omnipresent and ever-strenuous and unrecognized agents of infection. It requires no effort of mine to recall that, while as interne in Bellevue Hospital, the presence there of pyemia, septicemia, erysipelas and puerperal fever often halted the surgeon's best efforts of relief and forbade him to employ the most approved means of operative cure under the risk of increasing the death rate of the hospital. T believe that you will indulge me if I cast on this picture of unavoidable woe the resplendent sunshine of a little of the present outcome in preventive medical endeavor.

During the last twenty-five years it has been my honor and duty to be a visiting surgeon at Bellevue Hospital, a hospital devoted to the care of the unfortunate poor of the city, those whose habits and associations, in a large proportion of cases, do not fit them for the endurance incident to disease and injury. Yet, during this time, in Bellevue, plus eighteen additional years in St. Vincent's Hospital, largely devoted to the same class of patients, I have not met with as many cases of infective diseases of preantiseptic type as came under my notice in a month's time as a hospital interne before that period. And in this connection I desire to say that each of these hospitals was as successful in treatment as were any before that dark period, and since that time are unexcelled by none devoted to the same class of cases. I can say, without fear of gainsay, that hopeless cases of injury and disease for which no practical relief could be afforded before antisepsis and asepsis are now, as the result of the practical application of these remarkable agencies, rescued in large percentages (10 to 90) by the means of established operative endeavor—and so it is everywhere. Please remember in this connection, however, that the astonishing differences in these results is the consequence of increased knowledge and not of greater assiduity nor of more thoughtful care.

Enough has been said to emphasize decidedly the glorious results in medical endeavor—of preventive medical endeavor—of the last century and a half. The brilliant sunshine of the outcome in this endeavor mingling with its unshed tears would fashion a resplendent bow of promise gloriously betokening God's choicest gifts to man.

Vaccination, anesthesia, antisepsis and asepsis, antitoxin, the *x*-ray, the discovery of the tubercle bacilli and of the kinship between the mosquito and the yellow fever plague of commerce, and of malarial torments, are among the most potent and far-reaching beams of sunshine in medical endeavor, and which are constantly increasing in their brilliancy and beneficent power, adding comforts and life to the inhabitants of the world, and lessening correspondingly the tears and sorrows of the earth that cast a sunless shadow on all of life's endeavors.

THE CORRECTION OF EXOPHORIA BY DEVELOPMENT OF THE INTERNI.*

W. H. ROBERTS, M.D.,
PASADENA, CAL.

There are sins of omission as well as sins of commission in every profession. Oculists are guilty of the former when they treat asthenopic symptoms as though all were accommodative and none muscular. This paper does not aim at bringing out anything new in the way of diagnosis, or treatment, but simply recommends the necessity of determining the muscle balance in all refraction cases, and emphasizes a known and tried method of relieving the vast majority of cases in which exophoria exists. This subject has been impressed on me by seeing numerous cases that have passed through the hands of competent oculists, wearing glasses practically correct, with asthenopic symptoms unabated because of an unsought for and unrelieved exophoria.

I wish also to sound a note of warning against the indiscriminate performance of the various tenotomies, with or without advancements, wherever imbalance is found. While not opposed to operative measures when indicated, I believe they should only be performed when the lack of balance can not be cured or relieved by other measures, and then only by men who are so situated as to be in constant practice. I firmly believe that more eyes are injured than benefited when the muscles are cut by any but oculists of large experience, living in the larger cities and having sufficient clinical facilities for keeping well up in this class of operative work.

Orthophoria is an ideal condition of perfect balance, or equilibrium, of the external ocular muscles, in which the tendency of the visual axes is toward parallelism.

It is rather infrequent, however, that we find orthophoria, generally a slight esophoria being associated with our hypermetropic patients, and in our myopic, a slight exophoria. Most authorities are agreed that from one to two degrees of esophoria will enable the eyes to be used for near with greater comfort, owing to the slight excess of convergence, than will a condition of orthophoria. Slight degrees of exophoria in strong, robust patients may not produce symptoms of eye strain.

Exophoria, when seen in connection with its concomitant myopia, gives the least symptoms, since fewer demands are made on the adductors in this disease than in hypermetropia.

It is not the intention of this paper to go into the causes of exophoria or to take up the subject of muscle balance in an exhaustive manner, but to recognize the fact that in many of our patients a troublesome exophoria exists, and to report some cases to show that the condition can be entirely overcome, or relieved, by muscle exercise. No originality of method is claimed. We merely desire by showing results to encourage others to adopt this simple method of affording relief to a disturbing symptom.

A routine examination of the muscle balance should be made in every case refracted. It is not absolutely necessary to measure the degree of adduction or abduction, or of supraduction or infraduction. With the Maddox rod and the small point of light at six meters the balance for distance can be quickly determined, with sufficient accuracy for all practical purposes. In those cases where the Maddox rod test shows no exophoria for distance, and the glasses prescribed do not relieve all the asthenopic symptoms, it is well to make use of von Graefe's equilibrium test for the working distance, for frequently deficient convergence for 30 cm. will be found. If no attention is paid to the exophoria, either as regards the strength of the spherical portion of the lens ordered to correct the ametropia, or to the development of the weak interni, we shall fail to give the vast majority of our exophoria patients the relief they should have at our hands.

It is very essential that all refractive errors should be *carefully measured*, generally under a mydriatic, in patients under 45, for many cases of exophoria are undoubtedly produced, or at any rate, greatly aggravated, by an improper correction. In errors of refraction associated with hypermetropia the amount of the plus sphere must be very considerably reduced, or omitted, when exophoria is present, as such incentive to convergence as slight amounts of uncorrected hyper-

---

[*] Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

tropia give, are of aid in overcoming the exophoria. If myopia be present in connection with exophoria, a full correction of the myopia should be prescribed.

The general health should be considered and brought as near to normal as possible. The use of the eyes for close work should be restricted and out-of-door exercise advised. Dr. de Schweinitz recommends increasing doses of nux vomica, beginning with fifteen drops three times daily and running up to as high a dose as the patient will stand.

The method I use for developing the adductors consists of exercises at home, reinforced by regular visits to the office for supervision and additional exercise.

EXERCISES AT THE OFFICE.

Generally the proper ametropic correction is placed before the patient's eyes in a carefully centered trial frame and the attention directed to the point of light (or candle) six meters distant. Weak prisms, bases out, are put in the trial frame and the strength rapidly increased until the patient has difficulty in keeping the point of light (or candle) single. He is then told to close his eyes, slightly stronger prisms are inserted and on opening the eyes he looks at an ivory ruler held twelve to fourteen inches from his eyes, my body shutting off the point of light which is across the room. Telling him to look intently at the ruler I slowly back off towards the light and when I reach it I step aside and his gaze is quickly transferred to the point of light which is now usually single. If it is double I use weaker prisms until he can readily fuse the image and then gradually increase the strength. When the light is single after transferring his gaze from the ruler, I have the patient look steadfastly at it for a few seconds, then close his eyes for two or three seconds and if on opening them he can compel the lights to fuse, stronger prisms are placed in the trial frame. The rapidity with which the strength of the prisms can be increased, and the total to be overcome, must be determined for each case. Usually I add one or two degrees each time I walk across the room, until twenty-five or thirty degrees are overcome readily. It is not often necessary to overcome more than thirty or thirty-five degrees, but occasionally I run up to fifty. In all this work it is essential to stop short of actual fatigue of the external muscles, or no true development will occur. After the exercise the patient should sit a few moments with the eyes closed until they have somewhat recovered from the excessive convergence.

EXERCISES AT HOME.

The patient is given a pair of eight or ten degree prisms, mounted bases out, in a properly fitting straight temple spectacle frame, to be worn with or without the distance correction, as may be deemed best in each case. He is then carefully instructed in the use of the prisms as follows: To use the longest room or hall available, six meters or more being desirable. Then with the prisms properly adjusted before the eyes, to keep them closed until a lighted candle is brought in front of the eyes and twelve or fourteen inches distant. If the patient has some one to assist him with the work, the candle is then slowly carried across the room. If alone the patient slowly backs away from it, keeping the eyes and mind strictly on the light. After getting across the room the eyes are closed until the candle is carried back to the starting point, or if exercising alone the prisms are removed and not replaced until ready to mount on another pilgrimage. This procedure should be repeated until the light can be at once fused at six meters distance. In the beginning these home exercises should be gone through with morning and evening, the time occupied being about ten minutes. As the muscles strengthen, once daily will suffice. It may be necessary to increase the strength of the home prisms several times, depending on the results obtained. The exercises must be persisted in until the Maddox rod will show from one-half to two degrees of esophoria for distance, and the von Graefe test shows orthophoria for near. It is well to tell the patient at the outset that it will probably be necessary to keep up a moderate degree of exercise for an indefinite period after the methodical exercises are discontinued. If the athlete stops all training after his muscles are thoroughly developed, they will gradually lose their tone. So with the developed adductors; if all prism or converging exercises are stopped, some exophoria may again show itself, therefore it will be well to use the prisms for a minute or two daily, or the thumb exercise will do.

The following cases are reported to show what good results may be obtained by the methods just outlined:

Case 1.—E. G., male, aged 32, architect. This patient was referred to me through Dr. Geo. M. Gould of Philadelphia, and came under my care Dec. 18, 1903. For two years he had been unable to work at his profession owing to inability to use his eyes for close work. For a while he was a nervous wreck—which condition he ascribes entirely to his eyes—and was under Dr. S. Weir Mitchell's care. Dr. Mitchell sent him to an oculist, who prescribed O. D. + sph. 1.25, O. S. + sph. 1.00, which gave him no relief whatever. For some months he had been living a strictly out-of-door life, sleeping in a tent, hoping that his eyes would tone up and that the insomnia from which he suffered would disappear. He was greatly discouraged, and as he told me afterward, he would have gone back east forthwith had it not been for the fact that he could not look at the time table long enough to see what train he should take. He disliked to ask anyone for fear he should have to explain about his eyes. His examination showed O. D. V. 6/5 ??, O. S. V. 6/5 ??, 3° exophoria at 6 meters, 2° exophoria at 30 c.m.; adduction 10, abduction 9.

After careful mydriatic refraction I ordered, O. D. + sph. 0.50 ⊃ + cyl. 0.37 ax. 45 = 6/4, O. S. + sph. 0.50 ⊃ + cyl. 0.50 ax. 20 = 6/4.

He was given prism exercises at the office, supplemented by work at home with a pair of 8 degree prisms which were later increased to 12 degrees. By February he had ¾ degree exophoria for distance, and orthophoria for near. In March he had a slight esophoria for distance. He returned to active work in his profession in April, keeping up moderate exercise with his prisms. In May he had from 3 to 6 esophoria. When last seen in March of this year he reported his eyes perfectly comfortable. Adduction was 28 and abduction 9.

Case 2.—R. H., school girl, aged 16, complained of frontal headache, which came on only after use of eyes. O. D. V. 6/6 ??, O. S. V. 6/6 ??, 3° exophoria at 6 meters, 8° exophoria at 30 c.m.

Under a mydriatic no astigmatism could be found, either at trial case or by the retinoscope, only a slight hypermetropia, and this was not prescribed for. She was given the exercises at home, and at the office, and in just one month she had orthophoria. From that time on she was entirely free from headache.

Case 3.—Mrs. G. B. H. had been repeatedly refracted by one of the best oculists in Los Angeles, without any relief from her asthenopic symptoms. The glasses she was wearing were practically a full correction of her compound hypermetropic astigmatism. She showed 3 degrees of exophoria. I cut down materially the spherical portion of her lens, made a slight change in the cylinders and commenced muscle gymnastics. Her relief was prompt. On her return to her

matters

home in the east, three months after I examined her, her eyes were more comfortable than they had been for years. Until she came to me her muscle balance had never been tested.

CASE 4.—Miss E. F. A., aged 37, passed through the hands of the same oculist as Case 3 and with like results. She was unable to use her eyes with any comfort. Her lenses were practically correct, but she had 4½ degrees of exophoria, which had been entirely overlooked. Rest of her eyes from all close work for a time and moderate gymnastics worked wonders. In a little more than a month all her exophoria disappeared. In a short time more she had a slight esophoria and now she can use her eyes in moderation without any ill effects.

CASE 5.—T. G., school girl, aged 18. Asthenopic symptoms were unrelieved by the lenses she had been wearing for over a year, which were practically her full mydriatic correction. She showed 2 to 3 degrees of exophoria for both distance and near. I reduced the spherical portion of lenses each — 0.50 and prescribed prism exercises, with complete relief.

CASE 6.—Mrs. A. S. L., aged 50, wife of a physician, was wearing from one of the best oculists in the country, for reading, each eye, + sph. 1.50 ⊂ 3° prism base in. Her eyes were such that she could not read at all without diplopia. She showed 8 degrees exophoria for distance and 12 degrees for near. I was very doubtful in my prognosis of this case and rather advised a tenotomy, as her abduction was 12 degrees and adduction almost nothing. I made her rest her eyes, however, and gave here the exercises with astonishing results. She soon had an adduction of 33 degrees. With suitable correction, omitting the prisms, she is now able to use her eyes with comfort.

CASE 7.—Miss J. L., aged 23, came to me March 27, 1905, wearing a pair of 1 degree prisms, bases in, complaining of inability to use her eyes at all. Her vision was normal, adduction 14, abduction 9, 2½ degrees exophoria. I took off her prisms, started her on the exercises, and in two weeks her eyes were feeling much better. I did not see her again till June 27. She then had orthophoria for distance and near, adduction 30, abduction 9. She reported that she could use her eyes, all she wished, without discomfort.

CASE 8.—N. S. M., student, aged 18, consulted Dr. William Campbell Posey, Philadelphia, last fall, for sudden loss of vision in his left eye. Dr. Posey found a large lymph extravasation apparently from the superior temporal vein. Vision 2/60.

The young man had been indulging in sea bathing with great frequency. For some time he had had a thick discharge from his nostrils, evidence of some sinus involvement, and had been in the habit of sniffing the sea water through his nostrils. Dr. Posey made a diagnosis of thrombosis of the temporal vein, following a sphenoiditis, contracted by swimming. Dr. Posey put the young man on large doses of salicylate of soda. Active diaphoresis by hot air baths and pilocarpin was ordered every other day. In two months vision was normal. He then came to California and on May 10 consulted me. He had been studying hard for his Princeton examinations and his eyes felt strained and weak. He was greatly worried for fear he had injured his left eye by overuse. He was wearing weak sphero-cylinders, adduction 14, abduction 6, 1½ degrees exophoria. The ophthalmoscope showed evidences of an old chorioretinitis above the disc and in the foveal region, but not involving the macula. I made slight changes in the axes of his cylinders and ordered prism exercises. Improvement was immediate. After a short rest he was able to resume his studies with a tutor. By the middle of June he took his examinations without any evidences of eye strain. On June 26 he had 1½ degree esophoria, adduction 30, abduction 6.

I could give the histories of many more cases, but I think it unnecessary. The ones reported are fair examples of cases I meet every day. You will notice that of these eight cases two were emmetropic, and three were wearing lenses that practically corrected their refractive error but did not take into account the muscular defect.

I think the results obtained in these cases justify me in my enthusiasm for prism exercises and should reflect great credit on the originators.

DISCUSSION.

DR. G. C. SAVAGE, Nashville, pictured two ciliary muscles on the blackboard, and two internal recti; also two brain centers, one controlling the ciliary muscles and the other the interni (functionally). He said that there are two centers at the base of the brain, each of which is connected with two muscles, the ciliary and the interni. The centers of convergence and accommodation, he said, are so intimately related that one can not act without the other. The center of convergence, he assumed, is the third, and the center of accommodation the tenth, and asked what establishes the intimate relationship between the two. For every nerve impulse sent by the tenth center there is a corresponding nerve impulse sent to the two interni for convergence. Now, if there be orthophoria for distance and the tonicity of the ciliary and interni is normal, there can be no exophoria for near, for every time the ciliary muscle undergoes contraction the interni will also undergo the necessary contraction to converge to the object. Orthophoria for distance and esophoria for near is the normal condition. There is proper relationship as to tonicity between the ciliary muscles and the interni. Nature, he said, has placed in every brain centers for the correction of muscle errors. These centers are not the volitional centers; they are not in the cortex of the brain, but there is an individual center for every muscle connected with every eye for the correction of every condition that would cause diplopia. These centers, he believes, are in the base of the brain. There is the third basal center on one side and the third on the other. Volution has no influence over these basal centers, but influences the cortical centers only. In the proper test for heterophoria the basal centers are thrown off their guard and do nothing. He said that the Maddox rod does not offer a correct test for heterophoria, and said that the remedy is to increase the tonicity of the interni and that no operation is necessary. The muscles are to be exercised. Accommodation is strong, but convergence is weak; therefore, prism exercises are needed. That does not disturb the third center, but excites to activity the basal centers and they throw into a state of contraction the interni, and if such exercise is allowed to alternate with rest the patient will be cured.

DR. F. B. EATON, San Francisco, preferred to look at the subject from a clinical point of view. Eleven years ago, he read before this section a paper on the physiology of the ocular muscles, especially those of convergence, and he said that he has learned something in the eleven years that have followed. While Dr. Savage's demonstration from a theoretical point of view is impressive and experience will bear him out, yet he thinks the great error is not giving attention to the directions given last year by Dr. Ramsay, to build up the vitality of these patients. Dr. Eaton can overcome any amount of prisms and can converge one eye without the other, but he has exophoria for nearly 14 degrees. While this may be due to some disturbance of the vertical ocular muscles, his experience is that as the physician builds the patient up in a common sense way, he cures these muscle conditions. Otherwise it does not make any difference how much exercise is given them. Dr. Eaton thinks the condition is a neurotic one.

DR. DUDLEY S. REYNOLDS, Louisville, stated that he has seen many cases of heterophoria subjected to tenotomies, after Dr. Stevens' suggestion, and to a great variety of exercises with prisms, without satisfactory results. He believes that with a full correction of whatever error of refraction may exist, with systematic feeding and such medication as has been suggested by de Schweinitz, full doses of tincture of nux vomica, and perhaps change of scene, without any reference to the eyes at all, beyond the correction of the refractive error, a complete cure may be attained, and not in any other way.

Dr. William C. Posey, Philadelphia, declared that he fully believes that with the proper use of regular rhythmical exercises the condition of exophoria for near may be turned into esophoria for far, but for only so long as the prisms are used. When the use of the prisms is stopped the trouble returns. If the symptoms are to be held in subjection the exercises must be continued. One other point is that when the interni are exercised with prisms bases out, if the exercises be kept up a long time, Dr. Savage's hypothetical third center is also exercised, and it will be necessary to change the spherical lenses as the muscle power is brought up. Dr. Posey believes these are of value in bringing up the adduction. He has not been able to accomplish good results with bases up or down, or with the use of the cylinders, after Dr. Savage.

Dr. S. D. Risley, Philadelphia, said that he published a paper some years ago on abnormalities of ocular muscle balance, in which he outlined what seemed to him a just classification of these cases. The group of cases which depends on insufficiency of the interni, which does not exist until a number of convex glasses have been placed before the eyes, he denominated as relative insufficiency; that is to say, a patient who all his life has found it necessary to accommodate without converging might in this case converge without accommodating. When convex glasses are placed on a hypermetropic patient the condition which experience has taught him to exercise is disturbed and he is left with a relative insufficiency of the interni. These patients get well under the exercises set forth in Dr. Roberts' paper, but, there is another entirely different group which does not belong to these mentioned by Dr. Roberts nor to those spoken of by Dr. Savage; they are the patients who depend on faulty attachment of the muscles to the ball itself, deformity of the orbit. Given a deformed orbit, with different planes from the normal skull and the points of attachment may be distributed in many ways. The interni may be attached too far back, or the externi too far forward. The physician can exercise those patients until doomsday and while they may be made more comfortable for a time, as soon as the exercise is omitted their discomfort immediately returns. The muscle can never be strengthened. Dr. Risley doubts very much if any amount of exercise ever strengthens the ocular muscles, but it may teach some facility in using them.

Dr. John E. Weeks, New York, agreed with Dr. Roberts in his belief that there is a class of patients who can be benefited by these exercises, but said that there is a class that can never be benefited by prism exercises. It seems to him that there is a simple method of testing muscles to determine whether there is an absence of strength in one or the other, and that is by means of the perimeter, or better still, the tropometer of Stevens'. The power that the muscles have on the eye may be tested and one can judge very accurately whether a given case requires treatment with prisms, or operative interference. Dr. Weeks has not infrequently had patients come to him with a static exophoria of from 2 to 10 degrees and on measuring the muscles by means of the tropometer he found the actual rotation of the globe to be normal in every direction; with a rotation in, say 50 degrees; outward 45, approximately; and these patients have been benefited by treatment. When the rotation inward was perhaps 45 degrees and the rotation outward 50, such patients have not been benefited and operative procedure is necessary in the majority of patients to relieve them. He fully believes that there are anatomic defects in the muscles that require operative procedures for their correction. Each class of cases should receive its particular form of treatment and physicians have at their disposal the means of determining what that treatment shall be.

Dr. C. H. Williams, Boston, said that as the muscle is exercised and gets a little more facility or strength, the physician should keep on decreasing the correcting prism, keeping it always less than the amount of error, so that the muscle is always doing something to try to bring the eye to a proper position. In the use of the Maddox rod he finds that there is always a tendency to bring the line and the light together, a tendency to fuse images. That, however, [illegible] avoided very well by the use of a little apparatus which he showed before the section in St. Paul, consisting of a series of green figures with a red line running through them. Put in front of the eyes a pair of spectacles with one glass red and the other green, so that with one eye the patient sees the line and with the other the figures. With deficiencies in the vertical meridian especially, can a demonstration of a deficiency of one or two degrees be obtained, which could not be obtained with a Maddox rod, and these deficiencies in the vertical meridian he finds give the patients more discomfort than those right and left.

Dr. William Zentmayer, Philadelphia, said that a great many of these patients may be relieved without the use of prisms by putting on a very partial correction which relieves the disturbance created by correction of the hypermetropia. If the astigmatism has been corrected there is often relief of the asthenopic symptoms caused by the exophoria. He believes in prism exercises for exophoria.

Dr. Leartus Connor, Detroit, asked why most of the cases of muscle imbalance exist without producing any trouble and that only exceptionally is there trouble from this cause. That question he has not been able to answer satisfactorily, though the trouble may be called neurasthenic. In a practical way, he has found the use of the galvanic current of value in many instances. Another agent that he has found to be of use is very deep massage as near the medulla as possible, and of the vibratory variety. He does not know of anything that affords so much relief as this shaking up of the base of the brain. The occasional effects of such treatment are marvelous. Each case is a study of itself from the beginning to the end.

Dr. J. S. Kirkendall, Ithaca, N. Y., said that aside from medication directed to constitutional troubles, there are various reflex causes which should always be looked for. He recalled one patient who had been under the care of several prominent oculists and by the removal of a plug of wax from the ear he was able to relieve the symptoms. Another cause, the relief of which he has seen followed by good results, is an abnormal nasal condition, spurs, etc., in the nose. Many of these patients might be relieved by correcting these various reflex factors.

SUBCONJUNCTIVAL SALT INJECTIONS.*

S. D. RISLEY, M.D.

PHILADELPHIA.

Personal experience with subconjunctival injections of solutions of different crystalloid substances in the treatment of various forms of ocular disease, a study of the literature of the subject, and differing views entertained by some of my colleagues regarding the efficiency of the method, have led me to think that a discussion of the subject by this section would prove interesting and valuable. The literature is too recent and too well known to need extended references; I shall, therefore, confine these remarks to my personal experience regarding the groups of disease in which the method has proved useful, its mode of application and a brief consideration of the theoretical basis for its adoption. In my early experience, injections of solutions of the mercurial salts were first experimented with, but soon abandoned because of the severe pain they occasioned and the more or less violent reaction which was liable to follow their employment. Solutions of chlorid of sodium in varying strength were then substituted and experience soon excluded strong solutions of this salt. For several years, only the so-called physiologic salt solution has been employed at about the temperature of the body. In the cases here reported, this was the solution invariably used and extended experience has shown that it can be injected with practical impunity. In many hundreds of injections, I have not seen an instance of inflammatory reaction, or any thickening of the conjunctiva or subconjunctival tissues, or any adhesion of the tissues to the sclera, even when the injections had been made daily or on alternate days continuously for many consecutive weeks. While the results have often been disappointing, there has been no cause for regret because of harm having been done.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The following reported cases are taken at random to illustrate, not only favorable results, but groups of diseased conditions in which the method has proved a valuable addition to our armamentarium.

ABSCESS OF THE CORNEA.

Case 1.—G. G., aged 50, an Irish laborer, came to the Wills Eye Hospital with an abscess of the cornea situated near the lower limbus. There was a large hypopion with much infiltration of the cornea and the anterior wall of the abscess was breaking down into an open ulcer.

Treatment.—A Saemisch operation was performed, the man placed in bed and the usual well-known methods of treatment instituted. While they probably prevented the eye from passing rapidly into a state of panophthalmitis hypopion recurred and no progress was made toward recovery. Enucleation seemed inevitable, but before adopting this radical measure he was taken to the operating room, cocain solution instilled and an abundant injection of physiologic salt solution made under the conjunctiva at a point contiguous to the now large, open ulcer. It was immediately followed by a profuse sanguineous discharge from the needle puncture. In an hour the severe pain he had suffered subsided and in twenty-four hours the pus in the anterior chamber had disappeared. The injection was repeated on alternate days until four in all had been given, and hot saline stupes applied continuously.

Result.—The man made a rapid recovery and was discharged from the hospital with a circumscribed leucoma at the site of the original abscess.

INTERSTITIAL KERATITIS.

Case 2.—A Norwegian housemaid, aged 22, with pale blue irides, nearly white, flaxen hair; thick pendant lips, a flabby indented tongue and opaque, pale, muddy skin, clubbed fingerends, and a tall, lax, angular frame, came to the Wills Hospital for impaired vision in the right eye.

Examination.—There was some ciliary injection, there was no increase of tension, the iris reacted normally, the corneal reflex was not impaired, but there was a ring of gray opacity, apparently in Bowman's membrane, surrounding the corneal pole inclosing a nearly transparent center about 2 mm. in diameter. She was obviously in ill health, but there were no physical signs of cardiac or pulmonary disease. Menstruation was scanty and irregular. The central incisors were not notched.

Course of the Disease.—She received atropia locally, an improved general regimen was directed, and her service as housemaid was abandoned. Iodid of iron and arsenic were administered internally. The eye grew rapidly worse and photophobia increased, the opacity meanwhile spreading until the entire cornea was gray, rough and vascular, while the vision sunk until she was unable to count fingers. The left eye becoming also involved, she was admitted to the hospital, where, notwithstanding treatment, she was soon unable to go about without aid. The general health improved, but the eyes grew steadily worse, the opacity more dense and the left cornea also became vascular and the ciliary injection more marked.

Treatment and Result.—Daily salt injections were then begun as a last resort and other local measures omitted, except the hot saline stupes for an hour after injection. The improvement was at once manifested by diminishing discomfort and photophobia. In three weeks she could see her way about, and in six weeks she left the hospital, returning as an out-patient for the injection, which, however, were soon abandoned. In three months, the remaining corneal neubulæ could be discovered only on close inspection, and a year later vision was 6/60 in each eye with her correcting glasses.

Remarks.—In this patient all the usual means of treatment having failed, salt injections were followed at once by speedy relief, and ultimate cure of conditions which certainly threatened serious, permanent impairment of vision.

VASCULAR KERATITIS, WITH IRITIS.

Case 3.—Housemaid, aged 20.

History.—The patient had been under treatment at different clinics by able colleagues for more than two years. She was led to the Wills Hospital service by a friend and was admitted to the house.

Examination.—The palpebral conjunctiva showed no evidence of trachoma. The corneæ were gray and vascular throughout, there was marked pain, photophobia and lachrymation. Examination of the nasal passages and sinuses excluded them as an exciting cause.

Treatment and Result.—The salt injections followed by hot salines stupes were at once begun, and resulted in such rapid improvement that she was soon able to leave the hospital, returning alone as an out-patient on alternate days. The vascularity disappeared, leaving numerous gray spots and dots in the deeper layers of the cornea and a few posterior synechia in each eye. The deep ciliary injection and evident iridochoroidal disease slowly subsided under the iodids, and occasional subconjunctival injections for which she would voluntarily return because of the relief they afforded in the exacerbations of discomfort following exposure or use of the eyes.

Case 4.—High myopia, atrophic choroiditis, macular hemorrhage, commencing separation of retina.

Patient.—Mr. F., aged 29, traveling salesman, consulted me in February, 1905.

Examination.—He presented the following conditions: Right eye had been blind for several years from extensive detachment of the retina; left wearing — 6.50 D. V. = 6.60; fronto-occipital headaches with undue sensibility to light. The ophthalmometer revealed a considerable degree of uncorrected astigmatism, but no glass other than — 6.50 materially improved his vision. The entire fundus was fluffy, except the area occupied by an atrophic crescent at the temporal margin of the nerve. The vitreous was filled with a freely moving fine granular débris, seen with + 6 D. used as a magnifying glass. There was no impairment of the field of vision other than the narrowing due to the impaired light sense so common in choroidoretinal disease. The serious nature of his condition was explained and he was urgently advised to abandon his work and place himself under treatment.

Subsequent History.—He returned two months later in great alarm over a sudden loss of vision which had come on during sleep, two days before. His vision sunk to 1/60, with eccentric fixation, and the upper nasal field was wanting. The ophthalmoscope showed the vitreous filled with floating webs and shreds, an extensive gray opacity in the lower temporal ophthalmoscopic field, but little raised above the general level of the eye ground, but which extended upward, including the optic disc and macular region. At the macula, there was a horizontal band of hemorrhage, apparently lying between the choroid and the retina. The effusion or infiltration of the tissue was so great that the fundus could be studied without the aid of a concave glass, whereas, before the accident, — 6.50 at least was required at the fovea, and — 10. at the temporal margin of the nerve. His former glass — 6.50 D. did not improve, but rather impaired his vision.

Treatment.—He was placed in bed in a private room at the Polyclinic Hospital, bright light was excluded; blood was taken from the temporal and mastoid region. Iodid and bromid of lithium were administered internally, atropia was instilled and daily sweats secured by a twenty-five candlepower electric lamp hung under a tent formed by the blankets. His diet was regulated to meet the depleting influence of the treatment. His headaches rapidly subsided and the blind area in his field of vision diminished. At the end of two w
he became hysterical and homesick. He was therefor

from the hospital and domiciled at the house of a friend, but little improvement in the ophthalmoscopic appearances having resulted from the treatment, though the vision had risen to 6/60 with — 1 D. He then came to the office on alternate days *in a cab, and* received a copious physiologic salt injection remaining at the office in a recumbent posture for two hours. He then returned to his room and applied warm salt-water stupes, one hour in three, frequently opening the eyelids to freely bathe the conjunctival surface in the salt solution.

Result.—In a week, V = 6/30, eccentric fixation with — 1.50 D. and the cut in the field had disappeard. This improvement was followed by a partial relapse, but under the continued treatment the field was once more rapidly restored and he was permitted to return to his home on June 26, with V = 6/30 + with — 4 D. The central blind spot persisted, but its area was much diminished.

The gray infiltration of the fundus or subretinal effusion had disappeared, and a number of small atrophies in the region of the fovea were now present at the site of the hemorrhage. It remains to be seen whether, under prolonged rest and care this improvement can be maintained.

CASE 5.—Traumatic abscess of cornea with unguis and hypopion.

Patient.—A machinist, aged 30, came to the clinic of my colleague, Dr. Radcliff, at the Wills Hospital on April 10, three days after the removal, by a fellow-workman, of a chip of steel lodged in the cornea.

History.—I am indebted to his assistant surgeon, Dr. George Robinson, for the following condensed report: There was corneal abscess 2 mm. in diameter in the lower and outer quadrant of the cornea. The cornea was infiltrated with pus gravitating from the abscess quite to its lower limbus and the anterior chamber was occupied by a large hypopion.

Treatment.—Atropia was applied and the abscess was cauterized with carbolic acid. Blood was taken from the temple and continuous ice compresses were applied. The eye grew worse in spite of this treatment until April 14, when he received a normal salt solution injection.

Result.—At his next visit to the hospital, April 17, he was free from pain, the hypopion and unguis had disappeared, the conjunctival injection had diminished and the ulcer was clean and progressed to rapid recovery.

These cases are briefly reported to illustrate different groups of disease in which the injections have been used with rapid and signal benefit. The list could be indefinitely extended by the report of cases in which the course of disease was favorably influenced, but it is not my design to present statistics. Other groups might have been included, e. g., the use of injections in cases of uveitis with transient increase of tension and sand-like infiltration of the vitreous, or cases in which they were administered to hasten the absorption of swollen masses of cortex in the anterior chamber after discission of soft cataract; or cases of mild iritis with capsulitis coming on late in old people after cataract extraction, but to include them would have extended the paper beyond the time limit.

MODE OF OPERATION.

The purely theoretical consideration underlying the injection of solutions of crystalloid substances into a living animal membrane introduces us at once not only to a study of the anatomic relations of the lymph channels and apices of the eyeball, and to the nature of the tissue juices which occupy them under varying conditions of health and disease, but also to a consideration of the laws of osmosis and of dialysis.

The well-known law of osmosis of fluids, viz: that solutions of crystalloid substances of differing density or specific gravity, separated by an animal membrane, must diffuse through the membrane until they assume matter a uniform density, has suggested, for example, that in case of retinal detachment the injection into the contiguous lymph spaces of solutions of some crystalline salt of greater density than the fluid underlying the retina, through the law of osmosis, would tend to withdraw the retinal fluid to itself and so to exhaust the subretinal space. Clinical experiments based on these theoretical considerations, while in some instance of seeming benefit in hastening the disappearance of the subretinal effusion, have not, on the whole, given brilliant results in the treatment of separation of the retina. The suggestion, however, resulted in a series of more or less elaborate, laboratory investigations of the diffusion of fluids of various colloidal and crystalloidal composition until an extensive literature has been created.

From the point of view of the clinician, the results of these laboratory studies has been to offer but little encouragement to the advocates of subconjunctival injections. Indeed, if the clinician placed his trust wholly on the teaching of the laboratory experiments he would be inclined to abandon the method and to conclude that the apparent results which had at first excited his enthusiasm must have rested on faulty observation.

In witnessing the results which certainly followed the injection of solutions of crystalloid substances into or under the conjunctiva, it was natural to conclude that the resulting improvement in pathologic states was due to the injections; and in seeking for an explanation it was equally natural to turn to the well-known laws of osmosis or dialysis, the observer supposing, again quite naturally, that the diffusion of fluids through living animal membranes would be subject to the same laws which control the diffusion through organic membranes after their removal from the body. It was taught, therefore, *in the case of chlorid of sodium, for example,* that it acted as a lymphagogue; when the mercurial salts were employed that they acted not only as lymphagogues, but, in cases of infectious diseases of the eyeball, as disinfectants.

A careful study of the literature of experimental research, however, seems to show that those hasty conclusions are untenable; that any efficiency these injections may possess is not due to osmosis, or to their dialytic action, either of which would produce an acceleration of movement in the tissue juices and lymph currents; nor now to the antiseptic influence of the injected fluid, but is produced by a change in the composition of the aqueous humor, which, as a consequence of the irritation caused by the injections, becomes richer in albuminoids through the resulting congestion of the blood vessels and the increased *transudation of albuminoid* substances. The efficiency of these injections, therefore, is said to be due to the well known protective influence of the serum albumin poured out *into the* aqueous humor. In support of this view, we may recall the well-known fact that the composition of the aqueous humor is changed by paracentesis of the cornea, a procedure which not infrequently changes favorably the course of various pathologic states of the eye, e. g., in uveitis with transient attacks of increased tension of *the globe.*

When viewed from the standpoint of the clinician, it is difficult to accept the result of these experimental studies as representing the sole action of the subconjunctival injections. While it may be and probably is true that the irritation produced by the injections causes, through congestion, an increased transudation of albuminoid substances which are one of Nature's bulwarks against infection, it is not probable that these substances penetrate the tissues of the cornea in time to produce the results often speedily manifested after these salt injections. For example, the patient will often voluntarily bear witness to a clearing of the vision within a few moments after the injection, and in these cases I have frequently observed an unmistakable diminution in the corneal haze, so that the iris and pupillary area could be more clearly studied than before the injection had been given; an observation which is to be explained only on the supposition that the lymph channels of the cornea had been partly emptied of their abnormal contents into the lymph spaces surrounding the limbus. The corneal haze or impaired transparency is doubtless frequently due to an accumulation or congestion of migratory leucocytes which the lymph spaces and channels of the cornea, in response to the unusual inflammatory stimulus afforded by the existing pathologic process, and also, to the actual production of new cells from the division of the fixed corneal corpuscles. These products of inflammation clog or overload the exit into the conjunctival and subconjunctival lymph spaces with which they communicate and into which they empty under normal conditions, probably largely also through the perineural sheaths which, according to Piersol, are to be considered as lymph channels.

The fluids occupying the lymph spaces are, in health, probably derived from two sources; from the marginal vascular loops and by diffusion from the anterior chamber; the former being devoted to the nourishment of the anterior epithelium and the superficial layers of the substantia propria, while the latter supply the deeper portions of the cornea; not, however, by diffusion through the endothelial lining, but by a circuitous route through the spaces of Fontana at the angle of the anterior chamber, thence into the lymph channels of the sclera which communicate directly with those of the cornea (Piersol, Stadevini). It would seem, therefore, that while the diffusion of nutritive fluids into the corneal spaces occurs in the manner described, their principal exit is by the lymphatics of the conjunctiva, and in smaller part by the perineural lymph tracts at the corneal limbus. It is obvious that if these principal paths of exit are obstructed, either by pressure due to the surrounding inflammatory exudates, or are clogged by the excessive demand made on them in carrying away the congregated leucocytes and tissue juices invited to the cornea by irritation, that the fluids must accumulate both in the corneal spaces and in the anterior chamber.

Now it is probable that the injection of neutral, saline solutions of low specific gravity, rapidly dilate the channels of exit and, at the same time, dilute their contents, and so by a rapid diffusion of fluids hasten the flow of the diluted lymph and albuminoid substances through their normal channels. It is probable, also, that the emptied spaces are at once refilled by a fresh supply from the original sources which will be richer in albuminoid substances and withal would carry a fresh nutritive supply to the tissues. Some recent observations suggested by a renewed study of the microscopic anatomy of the ocular tissues, seem to show that the same result may be secured by other methods. The prolonged application of saline stupes, or of solutions of crystalloid substances of low specific gravity to the eye at the temperature of the body are useful if permitted to come directly into contact with the conjunctival sac.

For many years, I have treated stubborn cases of uveal disease by soaking the eyeball in an eye cup filled with warm Dobell's solution, made up with a reduced portion of carbolic acid. Until recently, it did not occur to me that its beneficial results were due to the osmotic diffusion securing a dilution of the contents of the lymph channels, but recent experiments with other crystalloid substances in solution of low specific gravity have led me to think that this is at least a plausible explanation. Furthermore, it awakens the inquiry as to whether this is not the *modus operandi* of many of the collyriæ which experience has proved useful in the treatment of ocular affections, e. g., solutions of alum, borax, zinc salts, etc.

DISCUSSION.

Dr. William Zentmayer, Philadelphia, said that while the salt solution may not produce any permanently disastrous results, it does sometimes produce disagreeable results. He saw a case of this kind in a young man who had been under treatment for some months for interstitial keratitis. The subconjunctival injections had been used and produced a marked bulbar conjunctivitis through blocking of the lymphatics. Some time later in a case in which he had been using the injections for detachment, the method had to be given up because of the severe reaction that followed. There was a great deal of congestion and after some weeks there appeared over the cornea of each eye a large crescentic patch of exudate, the surface of which was smooth in most places, but at various points there was ulceration that stained with fluorescein. The condition when he saw it last, was one of subsiding inflammation, but there was still considerable pigmentation of a yellowish color.

Dr. L. H. Taylor, Wilkesbarre, Pa., said that some time ago he saw Dr. Risley make these injections and went back home and used them on a patient under his care who had been treated for three months for opacities of the cornea. Dr. Taylor used the injections and the patient recovered so well that he was able to go to work and was temporarily lost sight of. He intends to follow up this plan of treatment later.

Dr. John E. Weeks, New York, agreed with Dr. Risley that the beneficial change or effect on the eye which is produced by the subconjunctival injections of solutions of crystalloid substances is not due to osmosis, but to influence on the circulation of the blood and lymph. Osmosis takes place when the difference between the densities of the fluids is relatively great. In edema of the glottis if a gargle of strong salt solution is used every fifteen or twenty minutes the edema is reduced in a short time. In all probability that is an example of osmosis, but such strong solutions can not be used subconjunctivally without doing damage to the tissues. The clearing up of the cornea is in all probability due to the change in the flow of fluid through the lymph spaces. The haziness is not always due to the presence of leucocytes and the clearing could hardly be attributed to the escape of leucocytes within the short interval mentioned, but it can be attributed to the removal of material from the lymph channels themselves. The reaction of the cornea in its different parts may be changed, that is, so far as alkalinity or acidity is concerned. It may be changed by sluggishness in the movement of the fluids. This is well illustrated in cases of scaling of the cornea by blood pigment. The hemoglobin enters the channels and when it approaches the center of the cornea an acid reaction may change it into hematoidin, which, in acid reaction, is a crystalloid and the blood pigment is crystallized in the tissues of the cornea. This will clear up to some extent and more rapidly if hot boric acid or chlorid of sodium solution is used. This suggests to Dr. Weeks' mind the probable explanation of the clearing up of the cornea under the influence of subconjunctival injections of saline solutions. The stimulation of the exudation from the blood vessels may also, and very probably does, take place as Dr. Risley has suggested.

Dr. A. E. Bulson, Jr., Fort Wayne, thinks that the re tion produced by the injections of normal salt solution frequently depend on the depth of the injection. W superficially, that is just immediately under the conjunctiva, it is just as efficient as when injected deeply. The reaction *may also be dependent on the frequency of the injections.* In quite an experience with the method he has found that some patients are particularly susceptible to the injections, some will have a marked reaction from small quantities, and still others will take large injections for weeks with no marked reaction. The effect on hypopyon and conditions of that kind, he thinks, depends largely on the character of the infection. He has found that the injections have little effect on the streptococcic infections or on more severe infections. The frequency of the injections and the length of time over which they are carried out, it seems to him, must also be taken into consideration if physicians are not to be disappointed in the results. A few injections will frequently not produce any decided result, whereas if carried out daily for four or five weeks they will.

Dr. S. L. Ledbetter, Birmingham, Ala., said that ten years ago he began the use of injections of mercury in this way and thought he got some good results, but the pain produced was so considerable and patients complained so much that he finally gave it up and began the use of the saline solutions instead. The results were so favorable that he prepared a paper on the subject of saline injections versus mercury injections and read it before the county society. He was much impressed with the benefits derived from it, but like other therapeutic measures that come and go, and on account of the difficulty to get patients to come with regularity and the inconvenience of carrying out the treatment, he lapsed into indifference and finally abandoned it for other methods. In the last year or so he has used almost exclusively the hot applications with the eye cup, using it two or three times a day and as hot as the patient can bear it. He found that he got practically the same results from the use of the hot normal salt solution in that way as by the injections. He believes that there are conditions in which possibly the injections will give results that can not be obtained from the hot eye baths.

Dr. Leartus Connor, Detroit, declared that the question is primarily one of fact and that Dr. Risley's observations, so far as they are positive, present facts. The reasons for the results may be many. Certainly there is a nervous element in the matter that has to be taken into consideration. The pressure on the eyeball, underneath the conjunctiva, must produce irritation of the terminal filaments of the nerve. The operation, therefore, is not only one of the relation of fluids, but is also one pertaining to the action of the nerves, by reflex irritation on the size of the blood vessels and rapidity of the currents flowing through them, making altogether a complex series of factors. For a great many years, Dr. Connor has obtained good results from the use of very hot water continuously applied; he has written one or two papers bearing on that. An additional help can be had by the judicious use of massage. He said that on returning home, after hearing Dr. Risley, he will try the use of these injections with more faith. The trouble in many cases is the objection of the patient to having a needle inserted in the eye. The other methods they do not object to.

Dr. Kaspar Pischel, San Francisco, said that some European writers state that they have used the subconjunctival injections of strong saline solution without causing particular pain, but if physicians make the same injections here they are disappointed. Patients here will not stand it like the patients abroad. The patients over there will submit to these procedures without grumbling.

Professor J. Hirschberg, Berlin, said that Europe is by no means a unity and that he could speak only of the part he knows. He sees also a great many American patients and he can not find so decided a difference between American and European patients. He uses the saline solution in exactly the same way as Dr. Risley and after employing it in thousands of cases he has not had a single patient complain.

Dr. S. D. Risley stated that he has not had any difficulty in having his patients, either private or public, submit to these injections. He purposely selected groups of cases ich have been stubborn and disappointing, and while

mo.

matte

abroad last summer some of his friends in England permitted him to see their work.

He had just left his own clinic, where a number of patients were getting well under the salt injections, and he suggested to Mr. Snell this method for cases of vascular keratitis, and he said he had had to abandon it because of the reaction and the great pain it caused. Dr. Risley said: "Well, Englishmen must be more susceptible to pain than Americans," and asked him his method of using the injection. The crux of the matter, Dr. Risley said, is the method. He has been doing it for ten years before venturing to say anything about it here and he has never yet seen any untoward result. The eyes will not bear mercurial salts injected under the conjunctiva. A patient who had been under Fuch's care in Vienna, for detachment, was sent here; he had been getting salt injections and had been getting very strong solutions which the eye would bear but once a week and which were placed deep in the orbit. Dr. Risley tried this, but not a second time. He found that Mr. Snell was giving injections in this way and the eyes will not bear it. Whether harm is to be done or whether the method is to be efficient or not depends on the manner of employing it. Dr. Risley has abandoned all but the physiologic salt solution because he abandoned the idea that it was by osmotic action that the benefit resulted. He believes it acts simply by dilation of the lymph spaces and dilution of the contents of the spaces and by hastening the current. The haziness of the cornea may be due to increased contents of the lymph spaces and the clearing up may be due to the change in the contents. He does not believe that it is due to a lymphagogue action or to emptying the spaces of leucocytes. In the thousands of times he has used the injections in the last ten years he has never seen harm result, but chronic conjunctivitis may result from the habit that many people have of daily washing their eyes in salt solution. He has again and again had patients of this kind. When cocain has been employed for a long while, and then salt solution used, it may set up a conjunctivitis, or when very strong solutions are used it may occur. He saw one case in which there was profuse hemorrhage after an injection, but on continued use there was no trouble. If a sterile solution at the temperature of the body is used and the bleb is not made too large—two or three minims are quite sufficient—simply lift up the conjunctiva, place the sharp needle point under it and raise a small bleb—no harm can result. It is often surprising to see how rapidly the bleb disappears.

INCISING AND SUTURING THE LIVER.

*A NEW METHOD TO RE-ESTABLISH A CONTINUITY AND FOR THE CONTROL OF HEMORRHAGE.**

JACOB FRANK, M.D.
Surgeon to the Marion Sims Hospital.
CHICAGO.

The object of all surgical operations, especially in abdominal work, should be to secure primary union. There is no reason why this principle is not as applicable to the surgery of the liver, providing a proper technic can be employed, so that when the cut liver surfaces are coaptated, the continuity of the organ will be re-established, and complete control of hemorrhage secured.

That liver surgery has failed to keep pace with the surgery of other abdominal organs can easily be ascertained on perusing the literature of the subject. The first and principal reason was the fear of hemorrhage, which, according to Kocher, is almost as true to-day as in the time of Theden, 1795. The lack of knowledge of the healing and regenerative power of the organ offers a second explanation. A third, the danger of infection, resulting in peritonitis, and, fourth, cholemia due to the escape of bile into the peritoneal cavity.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Injuries of the liver, accidental or intentional, even when slight, were regarded until recently as very serious. Thus the old idea that trauma of any sort involving the parenchyma of the liver offers a very grave prognosis, was still adhered to up to the beginning of the last decade.

Theden, as early as 1795, quoted by Mayer,[1] considered hemorrhage the primary danger even in superficial liver wounds, this danger increasing with the injury of large bile ducts. As the ducts and blood vessels are larger on the under surface of the viscus, wounds in this region were considered more serious than on the convex surface. "If not for the above two dangers," he says, "wounds of the liver would not be as fatal." The means employed in combating hemorrhage and cholemia in Theden's time were rest, antiphlogistics, vesication, and venesection. Of the direct methods for controlling hemorrhage, compression by tamponade was the most primitive. Mayer[1] has also shown that all surgeons up to the beginning of the nineteenth century regarded injuries of the liver as hopeless. Larrey,[2] 1812, wrote that laceration of the liver with the escape of bile into the abdominal cavity, would always prove disastrous. In 1864, Pirogoff[3] asserted that wounds of the liver were more frequent than the stomach and spleen, and in his experience were always complicated and resulted in death. Holm,[4] 1867, followed by Joseph,[5] Koester,[6] and Hüttenbrenner,[7] demonstrated the healing power of liver wounds. Von Bruns,[8] 1870, during the Franco-Prussian war, was the first to resect liver tissue after an injury, with good results. Luis,[9] 1886, employing a combination of different methods, was the first to remove a solid tumor, which proved to be a benign adenoma. The patient died from hemorrhage.

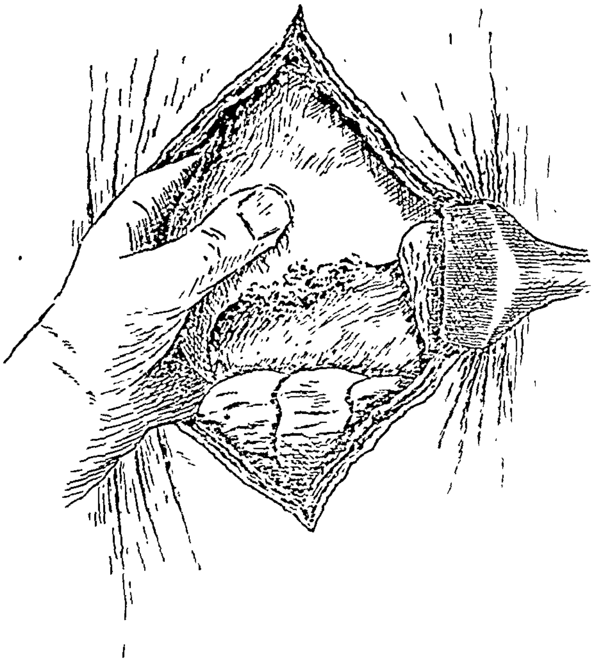

Figure 1.

A review of recent literature reveals the fact that modern surgery has done much to lessen the gravity of the prognosis in liver wounds, either accidental or those left by the surgeon after the removal of various growths.

The most complete statistics are those of Elder[10], in 1887. Of 543 cases collected by this author, he shows a mortality of 66.8 per cent.; 85.7 per cent. occurring in rupture; 55 per cent. in gunshot wounds, and 64.6 per cent. in incised wounds. These statistics are of more favorable cases, and do not include *injuries inflicted* by the surgeon while removing various tumors.

It remained, however, for Ponfick,[11] Meister,[12] and others to stimulate the surgeon and make him less timid in his attempts to attack this organ. They demonstrated on lower animals the regenerative capacity of that organ by removing as much as three-quarters of the liver, and showing a return to its normal size by compensatory hypertrophy and hyperplasia.

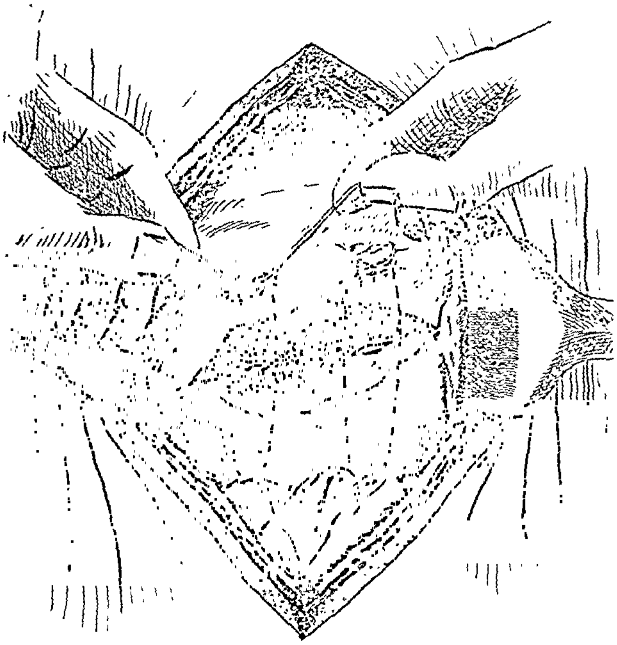

Figure 4.

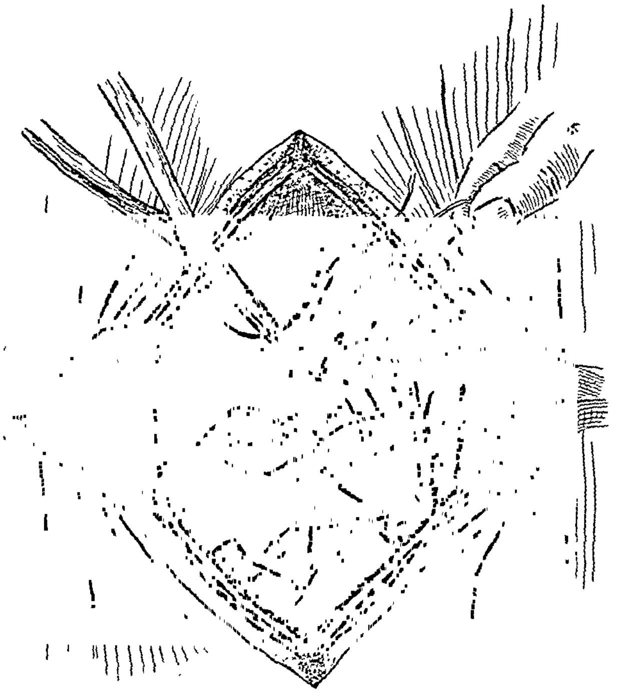

Figure 5.

The fear of cholemia due to the escape of bile, causing peritoneal involvement, as claimed by the older school of surgeons, had been refuted by Lücke and Tillman,[13] the latter citing a case of von Landerer, with injuries of the gall tract, and the withdrawal through five punctures of twenty-seven liters of bile. Peritoneal complications did not result from its presence, as bile is aseptic and at the same time antiseptic. I concur in these observations from my own clinical experience.

There were many methods in vogue up to the beginning of the last decade, all having as their basis the tamponade alone or combined with the suture, the suture alone being only a recent development.

Elliott[14] classifies the different methods as follows:

1. Packing the wound and fixing the stump extraperitoneally.
2. Packing and dropping the stump into the abdominal cavity.
3. Application of the thermo-cautery to stump and packing.
4. Combination of suture and packing.
5. The suture alone.

This is a broad classification. There are other means, however, that aid the above procedures, or are used in connection with other methods of handling the stump, as ligation of individual blood vessels, as advocated by Clementi[15] and others; ligation of vessels *en masse,* demonstrated experimentally by Kuznetzow and Pensky,[16] and confirmed by Auvray;[17] application of the tourniquet or constrictor, suggested by Terrillon,[18] followed by Israel,[18] Keen,[19] Carl Beck,[20] and others, using the same either for temporary arrest of bleeding, or for the purpose [illegible] constricting the growth to be removed [illegible] of the pedicle takes place. Hahn and Langenbuch[21] ligated the superior and inferior mesenteric arteries; Loretto,[22] Koenig,[23]

and others arrested bleeding by a running suture of Glisson's capsule. Tillman and Lücke[13] advocated the Paquelin cautery, which is still used by many operators. Suegiroff and Koslenko[23] utilized steam; Hollander and Abramowitz[24] used hot air. All of these procedures are employed by the different operators, each selecting the one best suited for the particular case. Other procedures in conjunction with the ones just cited are resorted to in handling the stump. It will be observed, therefore, that the principal object in devising these various methods, was the control of hemorrhage. The re-establishment of the continuity of liver surface was not considered, and hence the development of more proper methods of suturing liver tissue after the resection of large portions of that organ remained thus far imperfect.

Notwithstanding the modern advancement in surgery, Elliott asserts that packing of liver wounds seems to him to have settled surgical treatment of that viscus for some time, if not for all time. I am familiar with the reported results obtained by the combined method of tamponade and suturing. I am also cognizant of the fact that surgery of the liver needs advancement, and such advancement is surely coming, judging from the work already done with the suture alone.

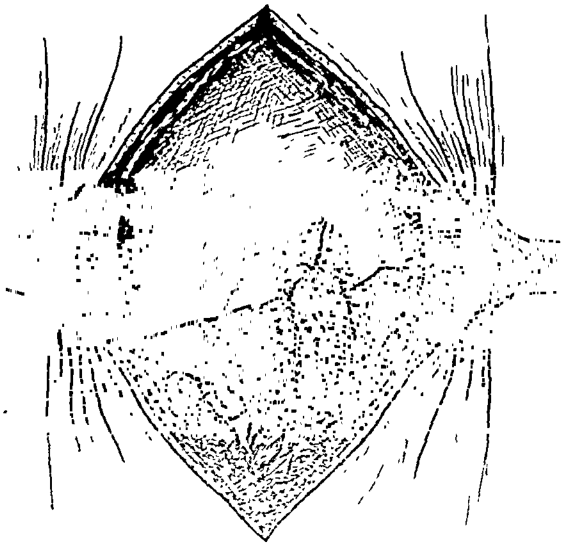

Figure 7.

It is only a very few years since the Mikulicz drain was employed to control oozing from raw surfaces denuded of their peritoneal coverings, but since we have learned to cover these denuded areas with peritoneum, the drain is dispensed with in a very large number of cases and the closure of the abdomen thus made possible. Therefore, that what is impossible and seemingly difficult to-day becomes possible and very easy to-morrow. The arrest of hemorrhage with the suture in the surgical treatment of wounds of the liver, after resection of large portions of same, has been demonstrated experimentally and clinically. Ceccherilli[25] and Segale[26] employed foreign bodies. One used perforated plates of whalebone, and the other ebony rings strung on catgut, both employing the devices for the support of the suture, which, according to these authors, completely arrested the hemorrhage, thus making the primary closure of the abdomen possible. These foreign bodies had to be left in the abdominal cavity, trusting to their encapsulation. Carl Beck[27] utilized bands of tissue from the abdominal wall, including peritoneum, fascia, and sometimes muscle. The suture is carried through these bands and utilized for its support. Kuznetzow and Pensky,[4] and also Auvray,[15] suture the liver in different ways around the part to be removed, then resect that portion of it surrounded by the suture, leaving a raw surface after resection is completed. These last-named authors demonstrated by ingenious experiments the possibility of successfully ligaturing liver tissue, since the walls of the blood vessels are sufficiently strong to sustain a weight of from 290 to 1600 grams without rupturing them, and that the isolated hepatic veins are stronger than the arteries.

The clinical results obtained by Carl Schlatter[28] in his reported cases demonstrate the effectiveness of the suture in liver wounds, and the future in store for the surgery of that organ.

He reports five very interesting cases:

1. Stab wound; prolapse of colon and omentum; profuse hemorrhage from liver; wound about one inch wide and so deep that finger-tip failed to reach the bottom; two deep sutures of heavy catgut, and two capsular sutures of fine silk; recovery.
2. Gunshot wound (revolver); severe hemorrhage; three deep sutures of heavy catgut to check the bleeding; good recovery made.

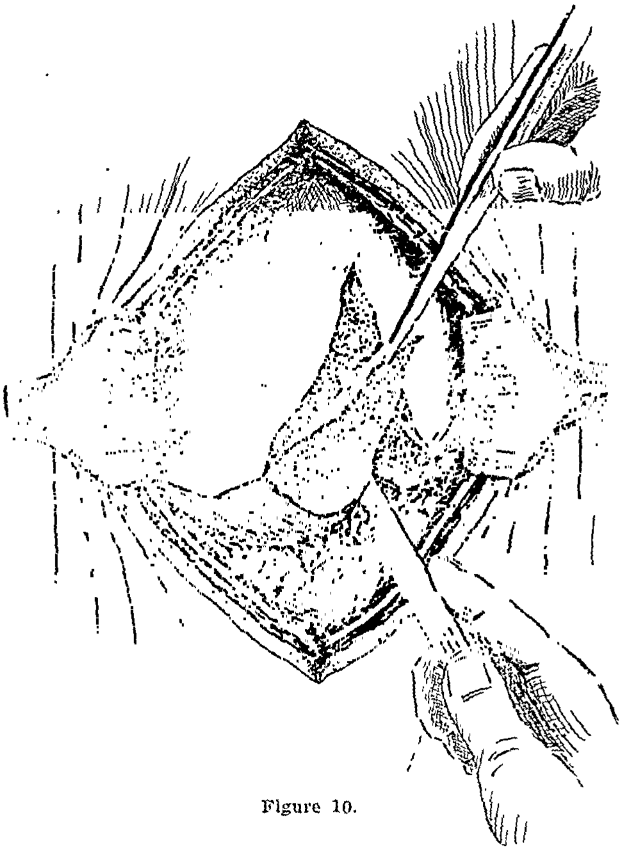

Figure 10.

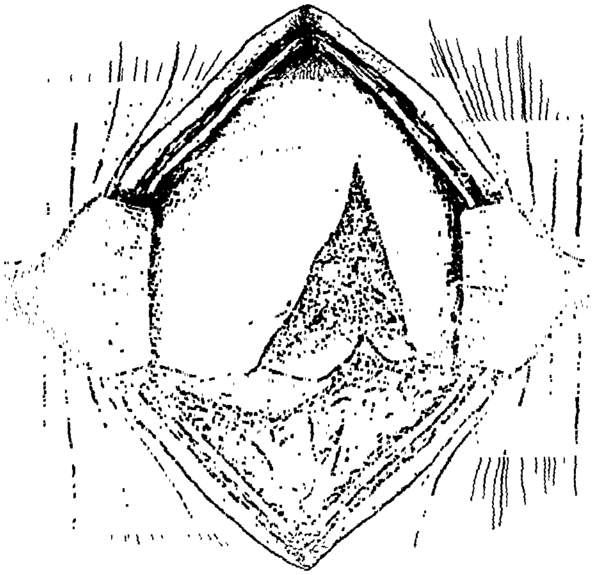

Figure 11.

3. Gunshot wound of liver by Folbert projectile; the track of the bullet *involved the stomach, jejunum, pancreas and the* left kindney; patient 17 years old; liver tissue was friable; six deep silk sutures stopped hemorrhage; death after eight hours.
4. Rupture of liver and right kidney; operation two days after; extreme anemia; laparotomy; suture of liver; hemorrhage stopped; saline infusion; death.
5. Almost complete sagittal rupture of left lobe of liver and profuse exudate of bile into peritoneal cavity; laparotomy; suture of liver fourteen days after injury; death.

In only one of these cases (Case 3) was there a tendency for the sutures to cut through the tissues. In this case silk was used instead of catgut, and the tissues were more friable than in the other adult patients.

It will be observed that the results with respect to checking hepatic hemorrhage by means of the suture are very satisfactory, and that catgut is preferable to silk. Schlatter's efforts at suturing large liver wounds are very encouraging. In view of the fact attending the results of the first two cases, Burckhardt's objections to the employment of the suture in large liver wounds do not appear valid.

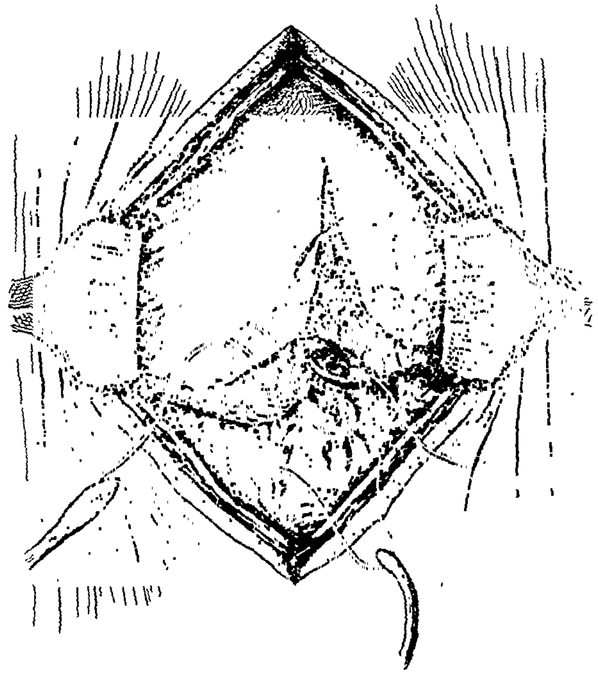

Figure 12.

After studying the subject, I concluded to conduct a series of experiments with the object of finding a method whereby large liver wounds could be successfully managed with the suture alone, re-establishing the continuity of the organ, completely controlling hemorrhage, and closure of the abdomen.

Within the past three years a series of eighteen experiments in all were conducted on dogs. Of these, two consisted in simply incising the liver through its entire thickness, dropping the organ back without suturing it, or making any attempt to control hemorrhage, which was profuse. Both dogs recovered.

In the remaining sixteen experiments the following plan was pursued: Let us suppose a portion of liver is to be resected for either a severe, extensive, crushed laceration, or a growth (Fig. 1). As a rule, these occur more often at or near the lower border of the liver. If the part is to be removed in a transverse direction, the liver tissue is incised on the upper surface, beginning at the healthy border on the hypochondriac side of the growth or injury, carrying the knife around the part to be removed to the border of the viscus on the epigastric side. The incision in the under surface is accomplished in such a manner that both will meet (Fig. 2). If desired, the incision may be commenced on the under surface and completed on the upper surface. The portion of liver thus removed by the junction of the two incisions is wedge-shaped, leaving the organ with two flaps forming a trough (Fig. 3). If the flaps do not fall into coaptation, more tissue should be cut away, as the perfect apposition of the flaps is essential for easy suturing. Before suturing the flaps, any bleeding is controlled either by a single ligation or ligation *en masse,* as the case demands.

---

[28] Beitr. f. klin. Chir., vol. xv, No. 2, 1896.

The arterial bleeding is easily distinguishable from the venous oozing, and is plainly seen coursing through the dark venous blood. The ligation is accomplished by passing a medium-sized catgut suture through the entire thickness of the liver surrounding the vessel or vessels; a single knot in the catgut is now made, and gradually tightened until the bleeding ceases; the ligation is then completed by taking one or two more knots (Fig. 4). This ligature may cut its way into the liver, producing a slight oozing, which can be controlled by pressure or a superficial suture of fine catgut. As soon as the hemorrhage is checked, the flaps are quickly coaptated, and with a long non-cutting needle, threaded with a medium heavy catgut, a running suture is commenced at one end and rapidly continued in the following manner: One suture is carried through the liver tissue near the bottom of the trough, and then one superficially, and so on alternating until complete closure. It requires but very slight tension to approximate the flaps. (Figs. 5 and 6). The mode of suturing can be varied according to the fancy of each operator. The main object is to bring the two flaps together, *obliterating all dead space. The continuity of the liver surface is re-established, appearing as if a new border was constructed. No raw surface or ragged edge is to be left.*

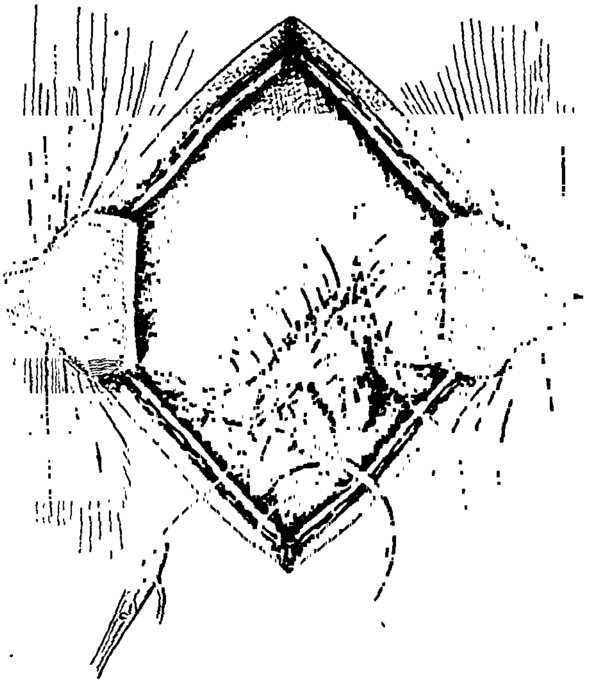

Figure. 13.

Let us assume again that a portion of liver is to be removed in a longitudinal direction to the viscus (Fig. 7). The following method is then pursued: A wedge-shaped portion of the entire thickness of the liver is first cut out (Figs. 8 and 9).

The two broad raw surfaces left by the removal of the wedge-shaped piece (Fig. 9) are now converted into troughs. This is accomplished by the excision of wedge-shaped pieces. The troughs thus formed each having two flaps (Figs. 10 and 11).

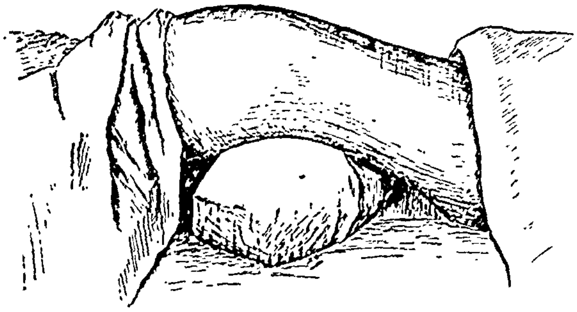

Figure 14.

When the operation is completed, the raw surfaces of the original V left are transformed into smooth, continuous liver tissue, assuming the form of liver borders, and the V space left persisting as a notch (Figs. 12 and 13).

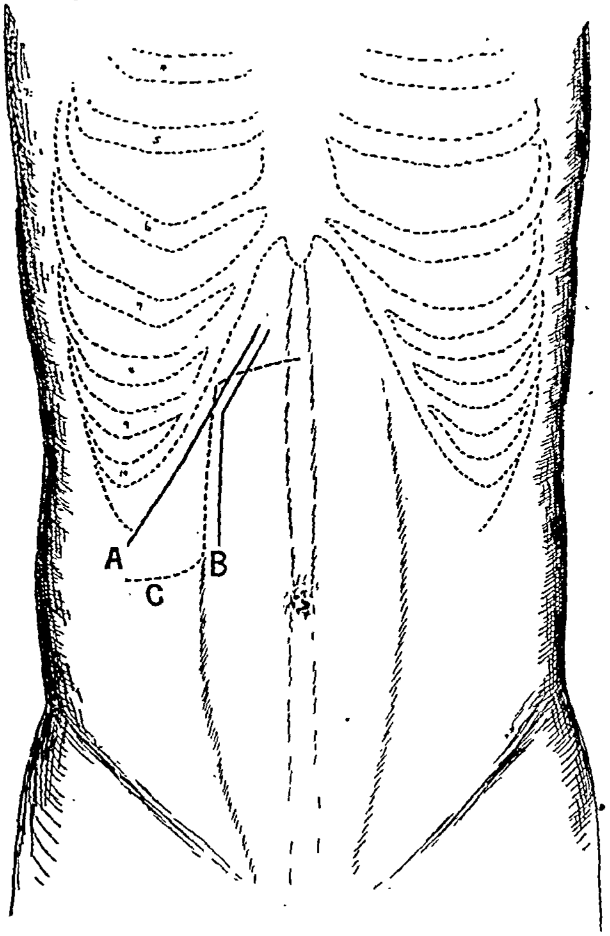

Figure 15.

This method of incising the liver facilitates easy suturing and does not require any tension on the sutures to coapt the flaps, and, at the same time, hemorrhage is successfully arrested, as was demonstrated in the sixteen experiments. There was not enough blood lost to produce shock or anemia in any of the dogs. Three died of sepsis. In none of the animals were there any evidences of either primary or secondary hemorrhage or escape of bile. When success was attained with this method of securing easy hemostasis in liver wounds, my curiosity still remained unsatisfied without any logical explanation for such accomplishment. It remained for Dr. Crile, of Cleveland, to offer his very practical explanation, based on animal experimentation and clinical observation, to strengthen my belief in the practicability of this method.

Dr. Crile, in his discussion of this subject, at the Pan-American Medical Congress, held at Panama, Jan. 3, 1905, made the following remarks:

> The research of Dr. Frank has given me a valuable suggestion. His observations on the arrest of hemorrhage are in accord with certain facts of the portal circulation, viz., the portal blood pressure is low even in the larger trunks—in the smaller vessels in the liver it amounts to but a few millimeters mercury. Since the principal hemorrhage is venous, it requires but a slight pressure distributed evenly over the bleeding surface to completely control it. The clean-cut incision, securing perfect apposition of the flaps, would require but slight pressure to control the hemorrhage. This pressure is well provided for by the method of suturing adopted by Dr. Frank.

In a recent letter from Dr. Wm. J. Mayo, of Rochester, Minn., I am informed of two cases in which the liver was injured while removing the gall bladder, causing considerable bleeding. In both cases the bleeding stopped promptly on applying the above principle. Dr. Mayo further states that from his experience in these two cases he has no doubt that this method will be of great value in direct excision of the liver.

I believe that with such results from a simple method the surgery of the liver will be revolutionized, and if put into practice operations on that organ will take rank with other modern operations.

My object is not to convey the idea that the foregoing method is ideal. Cases may present themselves where this procedure can not be carried out, on account of the inaccessible locality of the operative field. In the majority of the cases, however, I am convinced, from the limited number of experiments, that the method can be employed with little difficulty.

The question now to be considered is, What portion of the abdominal wall offers the best site for the operative incision? According to Schlatter, the upper portion of the liver, hemmed in, as it is, by the costal framework and by the diaphragm, is in a difficult position for surgical access. The left lobe and the irregular concave under surface is, on the contrary, more accessible. By moderate traction the anterior portion of the convexity, and in a similar manner the almost inaccessible posterior part, can usually be brought within reach, especially if the cushion or sand bag, as suggested by Mayo Robson,[29] is used (Fig. 14). If the site to be reached is located in the left lobe, or is undetermined, a median incision should be made. In wounds of the right lobe a curved incision along the lower border of the costal cartilages and to the right of the rectus muscle, as suggested by Kocher, is preferred (Fig. 15a). In some cases a combination of both, forming an angular incision, as practiced by Mayo Robson,[29] is to be employed (Fig 15b). Dr. Arthur Dean Bevan[29] suggests the use of an S-shaped incision in gall tract surgery, which may be used to good advantage in easily exposing the liver (Fig. 15c).

Since by far the greater number of wounds or growths of the liver are located on the ventral or lateral aspects of the viscus, these plans of attack will suffice. All incisions, whatever may be the choice, should be very large, in order to facilitate easy manipulation and quick work. For wounds located posteriorly, the lumbar incision will not answer, on account of the thickness of the muscular walls. The thoracic wall can, according to Lannelongue, be resected along the anterior portion of the eighth, ninth, tenth, and eleventh costal cartilages, as the pleura does not extend down to this part of the chest wall. Lannelongue's[28] method consists of an incision parallel with the thoracic border, and two centimeters above the same, beginning three centimeters from the border of the sternum, and ending at the junction of the tenth rib with its costal cartilage. The retraction of the divided muscles exposes the costal cartilages to be resected. They are then carefully freed from their attachments and cut through with cartilage scissors. If the ends of the ribs are now retracted and pressed apart, nearly the entire extent of the convexity of the liver can be made accessible.[30]

GALLSTONES IN THE COMMON-DUCT.*

WILLIAM D. HAGGARD, M.D.
NASHVILLE, TENN.

Gallstones in the common duct have been found once in every five cases operated on by Robson, and once in every seven cases of the Mayos. It is estimated that 67 per cent. occur in the duodenal end, 15 per cent. in the hepatic end, and 18 per cent. in the middle of the choledochus. They vary in size usually from a split pea to a nut-meg, although exceptional instances of much larger stones have been recorded. They are usually solitary, though more than one are frequently found.

They sometimes may remain many years. Moynihan speaks of one case removed after 9 years. They usually cause death in from 6 to 12 months from cholemia if the obstruction is complete and unrelieved. I have seen death ensue in 6 weeks from cholemia and infection, with intense jaundice and delirium, in spite of operation, which was only undertaken as a last resort, and which did not apparently hasten the end.

In acute obstruction Kehr advises against operation, not only on account of the high mortality attending it, but because a quiescent period usually ensues, in which jaundice and cholangitis are absent. Moreover he entertains the hope that the stone may, in some instances, finally escape and thus relieve the condition spontaneously. He makes the reservation, however, that it shall not be allowed to go unrelieved longer than 3 months, as usually beyond that time blood dyscrasia will have advanced so far that even operative relief cannot be invoked with safety.

Mayo observes, however, that "unfortunately the majority of common-duct patients have either never had an intermission or have passed beyond it and operation is no longer an election as to time, but a necessity and no matter how desperate, must be undertaken to save life."

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

If, on the contrary, there is no infection or jaundice or a quiescent period can be attained for operation, the mortality is, in the hands of the Mayos', only 2 per cent. contrasted to the general mortality of, say 10 per cent., in common-duct cases.

It was formerly the custom to look for the presence of gallstones in the feces after attacks of colics, and if found, it was with great delight and the hope that the trouble had reached a happy conclusion. Unfortunately the escape of stones does not occur as often as was commonly supposed, as the great majority of colics are unsuccessful in expelling the stone. Even if it is expelled, it is no evidence that others are not left behind. Indeed the surgeon hardly ever fails to find others in the biliary tract after the escape of one or more in the feces. I have reported one case of 100 stones removed from the gall blader after the patient had recovered a great many, and in another case herewith recorded there were 7 stones in the common duct after the patient had collected 45 during a period of 5 years. Mayo regards the passage of stone as an indication for operation and says, "in no case was operation performed on a patient who had passed stones by the bowel that the gall bladder did not contain more."

It must be remembered that large stones are more liable to ulcerate into the duodenum, stomach or colon than they are to pass through the common duct, and even then others, although much smaller, are likely to remain.

In the invasion of the common duct by stone, beside the colic which drives it, two other elements are concerned—obstruction to the flow of bile, and infection. In many cases the symptom of obstruction is not absolute, and infection is overcome. Unless the stone is tightly impacted, the downward flow of bile tends somewhat to wash away the infectious elements. This is wanting in the gall bladder, and hence infection there, if very virulent, goes on to suppuration, gangrene and perforation. The obstruction, too, is often imperfect, and bile flows alongside of the stone. Even if a round stone completely plugs the lumen, the bile accumulates behind it, the duct distends, and the stone floats back, thereby temporarily relieving the obstruction, and thus the ball-valve stone of Fenger alternately occludes the duct and then allows the bile to escape.

If the stone is impacted the jaundice is absolute. The common duct dilates. It sometimes attains a very appreciable size. It has been so distended as to be mistaken for a distended gall bladder, a pancreatic cyst and a hydatid of the liver. The pain is referred to the back under the right scapula. It is more prolonged. Vomiting is obstinate. Tenderness is present between the xiphoid and the umbilicus. Pressure may be so great as to erode mucous membrane and finally to perforate into adjacent viscera. Gallstones discharged in this manner sometimes cause intestinal obstruction.

The typical symptoms of gallstones in the common duct are very striking and characteristic. They may be enumerated in the order of their incidence in a given attack as pain, chill, temperature, sweating, hypersensitiveness, jaundice.

The pain in the beginning of an attack is usually paroxysmal and cramp-like. It may be dull, aching and rather constant. The patient may have shivering and rigors, or a distinct chill. The temperature then immediately rises, sometimes to 104. Profuse sweating follows and the temperature suddenly drops to normal. It thus has the "steeple" appearance on the temperature chart. Jaundice, if it occurs, usually makes its appearance in a few hours, or if already present, becomes strikingly deeper. The liver is tender and generally enlarged. This sequence of symptoms commonly subsides in a few days, only to go through the same cycle every few weeks.

The ague-like character often causes a diagnosis of malaria to be made, particularly if jaundice is absent or slight. It is also described as the "intermittent, hepatic fever of Charcot." During the jaundice the stools, of course, have the grayish, white, putty appearance, and the urine is beer colored. When the stone is dislodged, the stools are again colored brown with bile and the urine is no longer discolored by it. This very variation of jaundice and stools is most significant of calculous obstruction of the movable type. Frequent repetition of these attacks causes marked loss of weight from the recurring toxemia, and digestive disturbances. The spleen is usually enlarged.

If the fever, instead of intermitting, becomes constant, it indicates a general suppurative cholangitis. abscess of the liver or subphrenic abscess. The infection may extend into the pancreas. Opie has shown that a small stone lodged in the ampulla obstructing the papilla of the duodenum may cause the bile to be forced directly into the dust of Wirsung and cause an acute infective pancreatitis with fat necrosis and death. An acute accession of intense epigastric pain, with sudden shock, muscular rigidity, vomiting and collapse is indicative of this fatal catastrophe. There is no leucocytosis in this condition which distinguishes it from perforative peritonitis.

Riedel and Robson have shown that chronic pancreatitis may be caused from the gradual extension of a chronic infection from common duct gallstones. This, fortunately, is entirely curable by the removal of the cause and drainage. Prolonged jaundice vitiates the blood to such an extent that it leaks out of its proper channels. Subcutaneous hemorrhages occur and bleedings from the mucous membranes. This lack of plasticity of the blood renders operation in the presence of prolonged jaundice dangerous, as uncontrollable oozing often occurs from the incision, that is some times fatal. Chlorid of calcium is said, by Robson, to increase the blood-clotting power, but ecchymotic patches are a contraindication to operation without preliminary treatment.

Another result of prolonged gallstone irritation is primary cancer of the gall bladder and ducts. It was observed in 4 per cent. of 1,000 cases by Mayo. A hard, nodular mass in the region of the gall bladder, not tender associated with loss of weight, preceded by a gallstone history and followed by a lemon-colored, painless jaundice, is suspicious of malignancy.

Gallstones in the common duct are rarely attended with enlargement of the gall bladder. This physical sign serves to discriminate it from about the only other condition with which it may be confused—obstruction of the common duct with jaundice from other causes, principally cancer at the head of the pancreas. The jaundice in these cases is intense and unvarying, and the gall bladder is nearly always enlarged and painless. Courvoisier's law is, "In 80 per cent. of the cases of obstruction of the common duct due to stones there is contraction of the gall bladder, while in 90 per cent. of the cases of enlargement of the gall bladder the obstruction is due to other causes than stone."

The chief reason for a contracted gall bladder with common duct obstruction is the fact that infection of the gall bladder has probably occurred some time before, which has greatly thickened its walls, and perhaps fixed it by adhesions from a pericholecystitis. The gallbladder contracted in the preceding colics which started the stones on its migration from the gall bladder during the inflammation, and caused the walls to be stiffened with inflammatory exudate while thus contracted. It is, therefore, non-distensible and no amount of obstruction to bile can dilate it. The liver ducts yield and the cells are some times hindered in their secreting function by the pressure, causing the grave type of cholangitis, which together with infection renders this complication of cholelithiasis so desperate.

In distension of the gall bladder the deep, persistent jaundice generally betokens quite certainly the non-calculous origin.

Obstruction by stone and by tumor is differentiated in the following table adapted from Kehr:

	Gallstone Obstruction.	Obstruction by Tumor.
History	*Previous colics*.	*Absent*
Duration.	Years..	Only few months, at most a year.
Pain.	Always present.	Very rare.
Fever	Frequently present . . .	Usually absent.
Jaundice.	Variable comes and goes, stools alternately gray and brown	Very intense, stools continuously clay colored.
Palpation.	Gall-bladder small and not felt.	Large, elastic, distended painless tumor.
Spleen.	Enlarged	Normal.
Ascites	Absent	Frequent in malignancy.
Cachexia.	May be simulated in neglected cases	Pronounced. Left clavicular glands enlarged.

Obstruction also occurs from (1) cholangitis extending from cholecystitis; (2) adhesions; (3) stone in cystic duct large enough to produce pressure blockage; (4) chronic pancreatitis.

While jaundice occurs as described in the movable or ball-valve stone of Fenger, yet it is not always present where stones are in the common duct. In one of my cases during five years, 45 stones were, at various times in the common duct and were passed *per vias naturales,* and eight were found in a dilated duct at the operation, still he had never had jaundice but once and that for only a few days. Kehr found jaundice absent in 33 per cent. of his cases with stone in the common and hepatic ducts and Mayo says one-third of their patients had little or no jaundice at the time of operation; disappearance of jaundice does not necessarily indicate, however, that the stone has passed.

Jaundice is not, therefore, an infallible sign and should not be looked for in the great majority of cases of gallstones. The diagnosis can and should be made in most instances before the complications which cause jaundice occur.

In 1902 Robson operated 68 times, with mortality of 15 per cent. In his last 21 cases the mortality was 5.5 per cent. Kehr had 137 cases, with 9 deaths, or 6.5 per cent. Mayo's 137 cases had 16 deaths, or 11.7 per cent. Of the 16 deaths only 7 per cent. died of the immediate effects of the operation, and the other 4 per cent. recovered from the operation, but did not regain sufficient strength to leave the hospital. In this group was the unprecedented record of 30 cases without a death.

The most convincing plea for the earlier recognition of gallstone disease before the complications and common duct obstruction occur, these surgeons, out of 1,000 operations on the gall bladder and ducts did 820 cases where the disease and stones were still confined to the gall bladder with the most surprisingly low mortality of 2.4 per cent. This included acute and chronic infections, local peritonitis, complications, intestinal fistula, etc. In 416 cases of simple gall bladder disease, the mortality was less than 0.5 per cent— equally as good as the interval operation for appendicitis in patients of the same age and general condition.

Inasmuch as obstruction is primarily a purely mechanical condition, it requires purely mechanical treatment—operative removal. This gives opportunity for the relief of the other element—infection, by drainage, and drainage is the secret of success in the treatment of inflammations of the gall tracts.

NON-CALCULOUS CHOLECYSTITIS.*

DAVID S. FAIRCHILD, M.D.
Professor of Surgery at Drake University Medical School, Des Moines, Surgeon Mercy Hospital, Clinton.
DES MOINES, IOWA.

The literature bearing on diseases of the liver and bile passages has become voluminous and of late years, since operations for the relief from gallstones has become the recognized treatment for this disease, many books and other valuable contributions have been added having special relation to the surgery of the liver, bile passages and pancreas. Notwithstanding the fact that calculous cholecystitis or cholecystitis associated with gallstones have been well worked out, it is only recently that a class of cases of long-standing gall-bladder disease without gallstones has received attention.

Gall-bladder inflammations designated as acute or chronic catarrhal cholecystitis or the complicating condition known as empyema of the gall bladder or suppurative cholangitis involving the ducts of the liver are well described.

The special form of gall-bladder inflammation referred to in this communication differs somewhat in both the clinical and pathologic relations from the conditions above referred to on the one hand and from the calculous forms of inflammation on the other. It is not contended that the infection differs in character, but rather in degree; that gallstone formation does not occur even in long-standing cases, in fact it would appear that calculous formation was prevented by some condition present in the gall bladder itself.

The symptoms closely resemble those of gallstone diseases, but the classic gallstone colics are absent, although pains somewhat similar to those due to the passage of stones may occur.

The gall bladder has been explored under the diagnosis of gallstones and none found, which has led to the assumption sometimes that the stones had escaped or that there was an error in diagnosis. It has been observed, however, that drainage relieved the symptoms as effectually as in gallstones.

It is now an accepted fact that the chief cause of gallstone-formation is infection, and, while it is known that other germs may be the cause, the most frequent infection is the colon bacillus.

The manner in which the germs gain access to the gall bladder is immaterial here; their presence is the beginning of certain changes in the organ; the type of the change it is assumed will depend on certain facts in relation to the activity of the infection. Whatever secondary influences may be operative is immaterial, when it is accepted that germ infection is the essential etiologic factor. The fact that gallstones may remain in the bladder in many cases for an indefinite period without provoking symptoms indicates that the mere stone-forming process is not attended with a very active infection. It may, indeed, be true that active infection is inimical to the formation of gallstones; much support for this contention is found in the associated conditions which appear to have their development about the time symptoms appear, and correspond with those in gall bladders which are empty so far as stones are concerned but are in such a condition of disease as to give rise to distressing symptoms, or even be a source of danger to the patient's life. The discovery of stones in the gall bladder post-mortem without symptoms during life and the apparent chronicity of a calculous condition before symptoms appear, indicate that we must look deeper than the infection which has caused the gallstones for the serious symptoms which brings the patient to the surgeon.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

It is when the mechanical influences of gallstones come into operation that they become of surgical interest. First, when they attempt to escape through the cystic and common ducts. Second, when they traumatise the gall bladder and either increase the activity of the primary infection or lessen the resistance of the tissues.

In calculous disease of the gall bladder and bile tracts complicated conditions frequently exist. The simplest is the pure mechanical effects of the passage of gallstones, then comes the transitory or more continued toxemia from obstruction, and then the secondary mixed infections or the pus-forming activity of the primary colon bacillus which constitutes the beginning of stone formation, the immediate exciting cause being the trauma; usually the blocking of the cystic duct. The existence of pus in the gall bladder or an empyema may be said to follow the formation of gallstones if such be found in the gall bladder and not be coexistent primarily with the formation of calculi.

A separate but not altogether different condition is the infection of the gall bladder without the formation of stones. This has generally been designated as catarrhal cholecystitis, but this does not seem to be an entirely satisfactory definition, for it is not shown that the inflammation differs in its origin from the cholecystitis associated with gallstones, but, in fact, is dependent on the same kind of infection, differing only in degree or intensity. The gall bladder, when exposed, presents nearly the normal appearance, but on closer examination the walls appear to be a little thicker than is found in the healthy organ, and the lymphatic glands along the common duct are frequently enlarged. The bile is dark, thick and ropy, and the mucous membrane of the gall bladder is found covered with minute crystals of cholesterin; in some cases the mucous membrane is more or less actively inflamed or even ulcerated. When ulcerated patches are found, the presence of cholesterin crystals is less marked. It would appear that the cholesterin deposit marks a less active infection is rather more than less in the non-calculous yet both conditions may be found in the same gall bladder and may differ in time of development. In the latter the infection is too severe to result in the formation of calculi and prove inimical, even to the secretion of the cholesterin by the mucous cells, or, if the process has once commenced, is arrested by the increasing violence of the infection.

These same conditions may be found in calculous gall bladder, but mark different stages and different degrees of development, but in the non-calculous the milder or stone-forming period has never existed. Experimental evidence in support of the fact that the formation or non-formation of gallstones is largely dependent on the character of the infection as shown in the instances where injection into the gall bladder of virulent cultures produce severe cholecystitis and the injection of attenuated cultures may be followed by the formation of concretions, particularly if the flow of bile be hindered. Of course, it is not possible to state where the line may be drawn as to the condition in the gall bladder which may lead to the calculous and non-calculous inflammations. Clinically it is found that about 4 per cent. of the inflamed gall bladders do not contain calculi, and while the bacteriologic evidence does not appear to show that the infections differ, except in certain cases of empyema where a mixed infection has followed the traumatising or obstructing influences of stones, the infection is rather more than less in the non-calculous cases, and the other evidences of infection are even more marked.

To make our meaning more clear, we make the comparison between the calculous and non-calculous form during the formation of gallstones and not at a time when these stones, by trauma or obstruction, have set up secondary changes in the gall bladder or have invited a new or more virulent infection, or where incidentally a more virulent infection has occurred, in a pre-existent calculous gall bladder, when, according to the contention in this paper, gallstones cease to form on account of an influence exerted on the cholesterin secretion of the glands of the gall bladder.

Certain clinical facts and certain pathologic conditions appear to show that the infection in the non-calculous cases is more serious than the simple primary calculous varieties where the clinical evidence is the sudden, severe, classic, gallstone colic. The pathologic evidence lies in the thickened gall-bladder walls, the varying condition of the mucous membrane from a cholesterin crystal covering to a swollen, softened and, perhaps, ulcerated mucosa; the enlarged lymphatic glands of the common duct and in some cases a chronic, interstitial pancreatitis from the extension of the infection along the mucous membrane of the bile ducts to the duct of Wirsung and on into the pancreas, the organ becoming thickened and so dense as to give rise, at first, to the idea of malignancy. Not only does the infection extend outward, but not infrequently into the liver ducts, inducing a more or less severe cholangitis. In a certain number of cases it will be found that the infection has extended through the walls of the gall bladder and produced a pericholecystitis, as shown by adhesions particularly to the stomach.

The clinical evidence presented by non-calculous cholecystitis often leads to some confusion as to diagnosis. The clear and well-defined evidence presented by the passage of gallstones, the sudden onset of pain and its abrupt subsidence, and the prompt return of the patient to his former state of well-being, present quite a different picture from the more protracted sense of stomach sickness and pain in the region of the gall bladder.

Some degree of jaundice will be found in cases where the mucous membrane of the common duct is swollen, but is of short duration. Plugs of mucus may cause pain in passing through the bile ducts, but of less acute character than stones. The symptoms due to mechanical conditions, as the swollen mucous membrane of the common duct and the plugs of mucus, are supplemented by those of a more general character which are dependent on and are associated with infection as they involve the gall bladder, bile ducts, liver and perhaps the stomach and pancreas.

Chills and fever and pain in the region of the gall bladder and slight jaundice are not infrequently seen, but the jaundice is not very severe or very long continued, unless an associated calculous obstruction exists. The stomach attacks are more frequent and more troublesome than in uncomplicated calculous conditions, and if adhesions to the gall bladder exist some dilatation of the stomach may be found from interference with satisfactory stomach drainage. The symptoms due to the occasionally associated pancreatitis are too indefinite to be positively determined.

It is not intended in this discussion to include the phlegmonous forms of cholecystitis in which infection is so violent as to present the clinical picture and the pathologic findings of acute suppurative cholangitis, but rather the more chronic and less active forms of cholecystitis unattended with gallstone formation and with more or less frequent extensions of infection. In these cases the gall bladder is not contracted and there is no serious obstruction to the flow of bile into or from the gall bladder, and perhaps in the majority of cases the infection is confined to the gall bladder. In the milder forms there is no rise of temperature, or at least very slight, but the symptoms may be complex and lead to a doubt as to the exact diagnosis.

The results of operation in the milder cases of non-calculous cholecystitis are as good as in uncomplicated calculous cholecystitis. While in the more severe the mortality is higher and convalescence more protracted. In the milder cases a cholecystotomy with drainage for ten days results in a speedy cure. In the more severe infections a longer period of drainage is necessary, or it may be that a cholecystectomy is necessary. The more serious forms of infections are illustrated by the following case:

CASE 1.—A woman, 35 years of age, had suffered for a number of years from obscure symptoms of gall-bladder disease. She would have a slight chill, followed by a temperature of 101 or 102, pain and tenderness in the region of the gall bladder, and would be confined to her bed for a week or ten days, after which she resumed her household duties, but never appeared to recover her health fully. She lost somewhat in weight. Examination showed tenderness in region of gall bladder and some dilatation of the stomach. A diagnosis of gallstones was made. On operation the gall bladder was found free from gallstones, the bile was thick and ropy, gall bladder inflamed and thickened and adherent to the stomach. The adhesions were separated and rubber tissue interposed between gall bladder and stomach and the gall bladder drained in the ordinary manner. A fair amount of bile drained and a favorable result expected, but in twenty-four hours the temperature had reached 103, in thirty-six hours 106, and death quickly followed. There was no peritonitis and the fatal result was attributed to a cholangitis.

A second case illustrates a type in which the infection is less severe, but which had extended in a chronic form more widely.

CASE 2.—A man, 26 years of age, had had, four years previously, some attacks which had been diagnosed as gallstone colic, but for the past three years there were no distinctive attacks of pain, yet the stomach distress and nausea was more or less persistent, appetite uncertain and digestion much disordered. At times there was the faintest appearance of jaundice. Physical examination was negative and in the absence of evidence of disease of other organs it was determined that the gall bladder was responsible for the ill health. When the organ was exposed there was little in its appearance to indicate disease. It was moderately filled with bile and no stones could be felt. Its walls were somewhat thickened; the glands along the course of the cystic and common ducts were enlarged and at first communicated the feeling of stones in these ducts. The head of the pancreas was enlarged and firm, giving rise at first to the idea of malignant disease. The pathologic diagnosis was non-calculous cholecystitis with chronic pancreatitis from infection extending from the gall bladder. A somewhat prolonged drainage of the gall bladder resulted in a satisfactory recovery. Much anxiety was experienced for two weeks on account of a temperature from 101 to 103 degrees, which varied from day to day according to the amount of bile drained. Never before the operation while the patient was under our care had we found the temperature above 99.5. We do not attribute the temperature following the operation to any condition of the wound itself, but rather to an infection of the liver.

Our experience has led us to expect more temperature in these non-calculous cases than in uncomplicated gallstone involvement on account of the more widespread and more active infection. This seems to accord with general surgical experiences with operations in actively infected area. Our mortality from operations in this class of cases is even greater than in common-duct cases when the obstruction is not complete and when there has been no chills and fever. If in calculous cases chills and fever have occurred it may be assumed that an additional infection has supervened, or to the same cause and obstruction of the cystic duct, a pus formation and an empyema.

On theoretical grounds the cases considered in this paper indicate a cholecystectomy. In my opinion, it may be accepted as a rule that cholecystectomy is strongly contraindicated in all cases where there is a doubt as to the open condition of the common duct, whatever the condition of the gall bladder. In our cases of non-calculous cholecystitis both the cystic and common duct are freely open, except at periods of swelling of the mucous membrane, which are of comparatively short duration, and yet, notwithstanding this fact, infection has occurred and continued and spread out from the gall bladder at intervals, with greater or less degrees of intensity, to the liver ducts, common duct and even to the pancreas. The whole problem in treatment consists in drainage, and it may be assumed that, as the gall bladder is the chief center of infection, its removal would be the logical surgical procedure, and yet it may not be true that the additional advantage of external drainage may more than compensate for the general unsurgical procedure of leaving an infected structure which may, perhaps, demand a subsequent surgical consideration.

In deciding this question the surgeon will, no doubt, be governed by his ability to determine with absolute certainty if the common duct is equal to the exigencies of the case in affording all the drainage necessary. It would certainly be a much less serious mistake to leave a gall bladder that might safely come out than to take out a gall bladder that it much needed for drainage. The one could be corrected by a subsequent operation, while the other, it is feared, could not be corrected.

DISCUSSION.

ON PAPERS OF DRS. FRANK, HAGGARD AND FAIRCHILD.

Dr. A. MacLaren, St. Paul, Minn., predicted that Dr. Frank's statement would soon be accepted by all, i. e., that the liver is not a dangerous organ to attack, and that hemorrhage is not particularly to be feared. He considered Dr. Frank's flap methods for closing liver wounds very ingenious and very interesting. A simple over and over suture of catgut, passed with a large sized, full curved, round pointed needle and not drawn too tightly, has been found by Dr. MacLaren to control the hemorrhage very readily; if a wide V has been taken out, the raw surfaces must be brought together by transverse sutures of catgut placed in the same way. Recently three separate resections of the liver for gumma with simple over and over suture gave no bad results. Dr. MacLaren believes that the finding of gallstones in the feces is always associated with the presence of other stones in the billiary passages, as Dr. Haggard said. Jaundice is more common where a single stone is lodged in the common duct than where there are several. Dr. MacLaren recently found, after a careful study of his records, that he had operated on 10 cases of perforation of the gall bladder, two of which were of the non-calculous variety. Both perforations of the gall bladder were associated with small abscesses between the gall bladder and the duodenum.

Dr. Miles F. Porter, Ft. Wayne, Ind., although he admitted that the passage of gallstones usually means that there are more in the gall bladder, could not agree that it always means this. In two cases a number of stones were passed, and an operation showed that the last one had been passed. This is not of much importance, except from its politic side. It may be well to inform the patient that possibly the last stone has been passed. In any event, drainage of the gall bladder will usually be required. These cases may go on for a long period of time without symptoms to indicate the serious condition that is present. Dr. Porter has seen a case with a history of gallstone colic ten years before operation, and in the intervening time the woman had enjoyed good health, being free from symptoms pointing to the liver. Obstruction of the bowel finally called for operation, when the cause of the obstruction was found to be a large gallstone which had probably caused ulceration by pressure and this escaped into the bowel.

Dr. O. Grothan, St. Paul, Neb., considered it misleading to state that the passage of numerous stones by the bowel indicates that others will be found in the gall bladder. Six months ago he operated on a patient who for six or seven years had passed hundreds of stones, and in all this time at certain intervals had taken olive oil. He operated with good faith that he would find stones, but he did not. The gall bladder was very little thickened and the woman has been well since.

Dr. Charles M. Cooper, San Francisco, spoke from the neglected standpoint of diagnosis. We see many patients with pain in the upper abdomen; in some associated with vomiting; in others, not. The association is valuable as favoring the localizing of the seat of trouble in an abdominal viscus rather than in retroperitoneal structures, e. g., aortic aneurism in which there may be the most intense pain unassociated with vomiting. *Secondly*: Clinical re-examinations can not be made too frequently. The symptoms may be entirely masked at a first investigation, and yet a subsequent one may determine at once the organ involved. Thus, in a patient lately examined nothing abnormal could be detected. An equally full examination after a car ride over irregular streets demonstrated Head's area of hyperesthesia, a tender Robson's point, and pain associated with Murphy's maneuver. *Thirdly*: Mechanical stretching and relaxation of adhesions produced by change of position are of use. Certain movements or positions thus occasioning or relieving pain will sometimes suggest the organ involved and perhaps the nature of the lesion. *Fourthly*: Occasionally epigastric murmurs are associated with gall-bladder trouble, in some cases being directly due to a misplaced gall bladder, in others to a complication. *Fifthly*: The x-ray has a corroborative value in abdominal diagnosis. Dr. Cooper has plates which show liver tumors, a Riedel's lobe, a gallstone, shadows due to gall-bladder disease as proved by operation, and a fusiform dilatation of the aorta. The absence of leucocytosis during an attack of gallstone colic is by no means constant. Such attacks are often associated with septic absorption, and not infrequently there is marked leucocytosis which occurs quite quickly and disappears, as a rule, in a day or so, or may be in a few hours.

Dr. A. J. Ochsner, Chicago, emphasized the importance of making distinct flaps because on this depends to a great extent the ease with which the closure of the cut liver surface by first intention is accomplished. He also called attention to the importance of the formation of a clean surface. In a jagged, torn liver it is very much more difficult to stop the hemorrhage and to effect closure of the wound. A third point he mentioned is the slight amount of tension required in suturing a wound in the liver. If these three important points are borne in mind, it matters very little what else is omitted. The danger from hemorrhage amounts to very little if one comprehends these three important points. Dr. Ochsner said that there are a few points in Dr. Haggard's paper which should be emphasized. Acute obstruction of the common duct due to the pressure of stone should not be looked on as an emergency. There was a time when surgeons would operate on such patients at any hour of the day or night, and the mortality was very large. The patient practically always vomits bile before the obstruction becomes complete. This is due to an anatomic fact. The circular muscles of the duodenum are stronger at a point from two to four cm. below the entrance of the common duct than in any other part of this portion of the small intestine. Whenever there is an inflammatory condition, in any movable portion of the body there is some form of provision by which physiologic rest may be established. When anything passes through the duodenum at the entrance of the common duct there is a tendency for the emptying of bile into the intestines. The increased circular muscle fibers form a kind of sphincter which seems to serve the purpose of establishing physiologic rest when the common duct is inflamed as a result of the presence of a stone or sand in its lumen. Nature can be helped greatly in this matter, and the condition be changed from an acute to a chronic one. This can be accomplished by washing out the stomach and withholding food, so that there is no occasion for anything to be passed from the gall bladder through the common duct as the parts are put at rest. The acute condition will then subside. In many of these cases in which from one-quarter to two grains of morphia given hypodermically had no effect, the pain stopped within two hours after gastric lavage had been employed and did not recur so long as no food was given by mouth. It is well to prohibit the use of food by mouth until the acute symptoms have completely subsided and to operate before a recurrence of the attack.

Dr. J. H. Carstens, Detroit, drew on the blackboard a picture of an instrument invented by Dr. Ross. This instrument will get right under the gallstones. If necessary a couple of sutures may be inserted before using this instrument. Dr. Carstens had stated that he had trouble with the so-called gastroenterologists. They wash out the stomachs and give test meals; the patients are sent everywhere and are treated for acute gastritis. If Dr. Carstens had a case of so-called acute gastritis, with no other symptoms, he should at once decide that there was some gall bladder trouble. It may only be due to the bile being too thick, causing a partial stasis. This, he believes, is a gall-bladder disease, although possibly not gallstones.

Dr. W. J. Mayo, Rochester, Minn., said that after operations on the liver, the method of stopping hemorrhage based on the principle of Dr. Frank is well worthy of trial, and that he has practiced it with satisfaction in two cases since his attention was called to it. Dr. Dudley Tait has also brought out a method based on the preliminary injection of hot water into the liver along the line of proposed incision to stop hemorrhage. Dr. Mayo said that the whole question of gall-bladder surgery in connection with the common duct stone lies in the fact that when the disease is confined to the gall-bladder the operation is comparatively simple and will be followed by a very large percentage of permanent recoveries at a small risk, while, when the stones have entered the common duct the whole of the liver ducts are exposed to infection with possibilities of disastrous complications and secondary conditions. The operation is no longer simple, easy and safe. The question which the patient must consider is whether he can afford not only to continue to suffer from the gallstones but also to be exposed to the serious danger of liver duct infection or to the more remote but nevertheless possible chance of carcinomatous degeneration. In regard to jaundice, Dr. Mayo said that the history will usually show that there was more or less icterus at the time the stone passed into the common duct, although stones may remain in the common and hepatic ducts for years, without jaundice, giving manifestations of digestive disturbance. If the jaundice comes on without pain and does not change more or less in the early stages and especially if a tumor be present, malignancy is to be feared. With stones in the common duct the jaundice will be variable and changeable in the early stages, although later it may disappear entirely or become permanent from obstruction.

Dr. J. J. Hamilton, Caldwell, Idaho, related a case of a Scotchman who had some trouble with his gall bladder. A surgeon operated on him and removed 9 gallstones. Several others coming away from the wound from time to time a year later, the gall bladder again swelling up. The patient requested a young physician to operate on him without an anesthetic, and he refused to do so; the Scotchman returned home and operated on himself with a pocket knife. He removed several stones, made a good recovery and has since remained well.

Dr. Jacob Frank emphasized the importance of taking up liver surgery and putting it on a plane with appendicitis. In all the experiments on dogs there was no attempt to control hemorrhage, but he does not know how this would be in the human being. If there was a tumor situated somewhere along the lower border of the liver, and the operation was done quickly he does not think that there would be any danger to the patient. The dogs showed no signs of anemia. It is strange that there should be very little hemorrhage in liver operation. It looks like a great deal, but it is not, and simply bringing the flaps together controls it. Dr. Crile has explained to Dr. Frank why this is, stating that the blood pressure is very low in the liver. In bringing the edges together the capsule of Glisson is brought together.

Dr. W. D. Haggard said that when patients state they have passed gallstones, particularly those patients who have had the olive oil treatment, he always insist on seeing the stones, as these so-called olive oil stones are very frequent. The mortality is about 2 per cent. in stones of the gall bladder, and about 1 in every ten when the stones are in the common duct. It is not so much a surgical condition as one of cholemia. Operations should be avoided in acute obstruction of the common duct. Safety lies in the excellent preparation of the patient by preliminary treatment. Dietetic and other means must be employed, and the operation should be made a surface operation. If the gall bladder is used as a tractor, it is practically a surface operation.

Dr. D. S. Fairchild declared that it is the experience of many that some of the most serious difficulties arise in the cases in which there are no stones; the cases in which the infection extends from the gall bladder to the liver and pancreas, although this applies to only a very small percentage of cases. It should not be assumed that there are gallstones simply because symptoms are present which are referred to the stomach and gall bladder.

The "Vestiaire" of the Hospitals.—This is the name of a French society which recently held its first annual meeting. It was organized for the purpose of supplying comfortable and respectable clothes for persons just dismissed from the hospitals. As a rule, the poor reach a low ebb in their fortunes before they decide to enter the hospital, and they are financially stranded when they leave it, which interferes with their finding employment. The society already has over 4,000 members, and has collected 12,000 garments and a capital of nearly $4,000. Subscriptions and gifts of clothing are sent to the central office at Paris, rue de Grenelle 42. Debove, dean of the Paris faculty, is president of the new society.

SURGICAL BACTERIOLOGY OF THE MOUTH.*

A. H. LEVINGS, M.D.
MILWAUKEE, WIS.

In this section, devoted as it is to stomatology, I think that we all must admit that the bacteriology of the mouth should play an important rôle. The subject is of importance to the physician because here we find local manifestations of many constitutional diseases, such as influenza, diphtheria, smallpox, varicella, measles, scarlet fever, tuberculosis, syphilis and scurvy, in some of which at least the specific micro-organisms may be found in the oral cavity. There are also a variety of pathologic processes which occur within the mouth or adjacent bones, many of which are due to pathogenic micro-organisms. Among these may be mentioned tuberculosis, actinomycosis, osteomyelitis, thrush, anthrax, erysipelas, ulcerative and gangrenous stomatitis, pyorrhea alveolaris, and caries of the teeth. To any one who is doing mechanical or surgical work within the mouth the subject is of interest because of the frequency and variety of germs encountered, and, as is well known, these germs may at any time, unless precautions are taken, infect the wounds made. This fact I have seen most painfully and forcibly illustrated by the death of two patients from a most virulent pyogenic infection following the extraction of a tooth.

With the inspired air, with the food and drink taken from our fingers and from foreign bodies introduced into the mouth, a great variety of pyogenic and pathogenic germs gain an entrance to this cavity. The natural warmth and moisture of the mouth, as well as the organic matter so frequently present, then make it a most favorable site for the growth of bacteria. This is true even in healthy persons who do not properly cleanse their mouths, but especially so in those whose oral cavity is the site of some pathologic process.

A very commendable work has been done in the bacteriology of the mouth by a number of investigators. Among these may be mentioned Miller of Berlin, Vignal, Fluegge, Sanarelli, Netter and others. These results have not been uniform, as one might readily expect, for even in the examination of healthy mouths there is a wide difference in the bacterial contents.

For the purpose of carrying on these investigations, the subject was divided into five parts. The first class included clean mouths; the second, ordinary kept mouths; the third, filthy mouths; the fourth, tobacco chewers' mouths, and fifth, mouths in which there were distinct pathologic processes.

In the examination of the first four groups, one hundred swabs were taken from different individuals, dividing them as equally as possible into the different groups. The first twenty swabs were taken from mouths which were sweet and clean and in which the teeth were well preserved and clean. These swabs were washed in a normal salt solution and then used as a medium for further study. First hanging drops were studied. In all instances the hanging drops showed thousands of bacteria of different forms and shapes. Micrococci were found in all of the mouths examined. These varied somewhat in size and number; the most frequent were staphylococci, which were present in every case examined, and in 15 of the 20 cases examined *Micrococcus tetragenus* was found, while in 6 of the cases sarcinæ were discovered; of the bacilli, all shapes and sizes were found. Some of these were motile and others non-motile. Some of them were spore-forming and others non-spore-forming; of the spirillæ, both long and short were found. These salt solutions were then plated on agar and gelatin and incubated for further study. On all of the plates the colonies were too numerous for study and it was found necessary to make dilutions of 1 to 100 in order to get the colonies fewer for individual study. These colonies were stabbed off and agar, bouillon, gelatin and Dunham's solution, lactose and glucose bouillon, fermented tubes, lactose and glucose agar shake culture made, besides milk and litmus gelatin. By a minute study of these cultures it was shown that thousands of bacteria noted in the first examination were innocuous and that all but the streptococci (noted in two cases); *Bacillus coli communis* (found in three cases); *Bacillus subtilis, Staphylococcus* (found in all the cases), and the *Micrococcus tetragenus* (found in fifteen cases, were non-pathogenic. Of the non-pathogenic germs a large number were acid and gas producers. Many, though, were species of putrefactive bacteria. There were also a large number of micro-organisms which could not be identified, but which seemed to correspond with those described by Professor Miller of Berlin.

---

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

THE ORDINARY KEPT MOUTHS.

In making a study of thirty of these cases, they were found to differ from the well-kept mouths by the fact that the micro-organisms were much more numerous. This was especially marked where small pieces of putrefactive matter were present in the cavities of decaying teeth. The majority of micro-organisms in these cavities were, however, putrefactive germs, and, as they grow with great activity, they may kill out the other germs. In two of the thirty cases the bacillus of influenza was also found.

THE STUDY OF FILTHY MOUTHS.

In the majority of these cases there were pathologic processes going on in the mouth, such as decayed teeth, suppuration of the gums or small ulcers. In two cases thrush was present. In all of these filthy mouths millions of bacteria were present and a much larger per cent. were virulent. The pneumococcus was present in ten of the thirty cases. In the cavities of decaying teeth large numbers of acid producers and putrefactive bacteria were present. In the cases of pyorrhea large numbers of both *Staphylococcus pyogenes aureus* and *albus* were found. In three cases of abscess *Staphylococcus pyogenes aureus* was demonstrated. In two of these there was also *Staphylococcus pyogenes albus*, and in one *Staphylococcus pyogenes citreus*. In a large number of these mouths *Micrococcus tetragenus* was also present. In a great many cases putrefactive germs were well pronounced and gas formation very marked. The foul breath in these individuals is probably due to these obnoxious gases given off by the activity of these germs.

TOBACCO CHEWERS' MOUTHS.

An examination of these cases shows that the tobacco chewer's mouth is more filthy than the ordinary filthy mouth. The examination also shows that the tobacco had no restraining influence on the growth of bacterial activity. The majority of these mouths were pathologic and contained decaying teeth, small ulcers and suppurating processes about the teeth. It was not apparent that the tobacco was the cause of the decay, only that the individuals were less careful of the condition of their mouths.

BACTERIA SPREAD BY COUGHING.

Examinations were made to determine the number of bacteria thrown from the mouth in ordinary conversation, forced, explosive expiration and in coughing.

A plate exposed for two minutes just in front of the mouth during ordinary conversation showed 235 colonies. A plate exposed for one minute at the distance of five feet during forced expiration showed 105 colonies. A plate exposed for one-half minute at the distance of five feet during explosive expiration showed 192 colonies. A plate exposed at a distance of ten feet showed 35 colonies after five forcible coughs. A plate exposed at a distance of 20 feet showed a development of 23 colonies after ten forcible coughs. These examinations were made in a bathroom which had no ventilation and was practically free from germs, so that a plate exposed for five minutes in quiet showed the development of but three colonies. In other experiments plates were exposed at the distance of five feet and coughed at five times forcibly with one, two and three thicknesses of gauze in front of the mouth. The plate exposed with one thickness of gauze in front of the mouth showed a development of 156 colonies. The plate exposed with two thicknesses in front of the mouth showed a development of 35 colonies, and the plate exposed with three thicknesses in front of the mouth showed a development of 8 colonies.

EXAMINATION OF BACTERIAL CONTENT OF SPECIAL PATHOLOGIC PROCESSES.

Case 1.—A child 3 months old. A swab was taken one day after an operation for hare-lip, before cleansing the mouth. The swab showed the presence of *Staphylococcus pyogenes aureus* and *albus* and the *Micrococcus tetragenus* in large numbers. There were also many non-pathogenic bacteria. After the mouth had been cleansed by washing it out with peroxid of hydrogen in water, 1 part to 3, a swab was taken which showed the *Staphylococcus pyogenes aureus* still present, only in much fewer numbers.

Case 2.—Epithelioma of the lower lip. Swab taken before cleansing showed *Staphylococcus pyogenes aureus* and *albus* and *citreus*, the *Streptococcus pyogenes* and large numbers of putrefactive germs, as well as many non-pathogenic bacteria. After a thorough irrigation with normal salt solution, a swab was taken which showed an absence of the streptococcus; the diminution in number of the other germs, although they were still present in great quantities.

Case 3.—Carcinoma of the upper jaw producing ulceration of the gums. A swab taken before cleansing shows a large number of acid producers, putrefactive bacteria, *Staphylococcus pyogenes aureus, albus* and *citreus*, a number of streptococci and *Micrococcus tetragenus*. Large numbers of fungi of different kinds were also found on this swab. The swab taken after irrigation with normal salt solution showed little improvement in the bacterial content of the mouth.

Case 4.—Epithelioma of the tonsil. Swab taken before cleansing the mouth showed thousands of bacteria of all kinds and shapes. There were present the *Staphylococci pyogenes aureus, albus* and *citreus*, large numbers of *Streptococci pyogenes* and also the pneumococcus. The swab taken after the cleansing with normal salt solution showed a great reduction in the number of germs, but the pus cocci were still present in small numbers. The pneumococcus could not, however, be demonstrated.

Case 5.—Epithelioma of the cheek. Swab taken before cleansing showed a great number of germs of all sizes and shapes and also a great number of fungi, including yeast fungus. The majority of these germs were putrefying bacteria. The pus germs in this case were present, but not so numerous. After an irrigation with one-half gallon of normal salt solution through a fountain syringe, the swab taken showed but few pus cocci, while the putrefactive germs and the fungi were greatly reduced in number.

Case 6.—Sore mouth in child. Swab taken before cleansing showed numerous bacteria, some of which I was unable to identify. There were also large numbers of actively motile bacilli, as well as acid and gas producers. After cleansing with a mild antiseptic, but very few bacteria were found.

Case 7.—Sore throat. Swab taken before cleansing showed numerous staphylococci and long threads of streptococci. The swab taken after gargling for five minutes with a teaspoonful of an antiseptic solution in a small glass of water showed very few pus germs and these seemed innocuous, for they would not grow on culture media.

Case 8.—Acute pharyngitis. Swab taken before cleansing showed a large number of staphylococci, streptococci, also the bacillus of influenza and Friedlander's bacillus. Swab taken after cleansing with antiseptic gargle showed numerous staphylococci and streptococci, but these seemed innocuous, as there was but a single, thin growth of *Staphylococcus pyogenes aureus*.

Case 9.—Canker of the mouth. Swab taken before cleansing showed numerous forms of bacteria, including staphylococci and a large branching fungus. Swab taken after cleansing with peroxid of hydrogen was negative.

Case 10.—Patient had had both tonsils removed several days before examination. Swab taken before cleansing showed great masses of staphylococci and streptococci. The streptococci could not be cultivated. The staphylococci on cultivation proved to be *Staphylococcus pyogenes albus* and *aureus*. Swab taken after cleansing with peroxid of hydrogen showed only a small number of staphylococci which were grown with great difficulty and did not fully regain their power or growth until they were transversed three times onto fresh nutrient agar and incubated at 37 degrees.

Case 11.—Girl, 19 years of age. Patient has consumption and several cavities in one lung. Swab taken before cleansing mouth showed a large mass of bacteria, pus cells and epithelial cells. A simple covered glass smear stained for tubercle bacilli showed them to be present in large numbers. Besides, there were large groups of staphylococci and long threads of streptococci. There were also numerous ordinary forms of bacilli and fungi. The presence of pneumococcus was demonstrated. The swab taken after cleansing the mouth and throat with antiseptic showed staphylococci and streptococci, a few tubercle bacilli together with some pus cells. These germs, however, could not be cultivated.

Case 12.—Girl, aged 10 years. Part of tonsil, soft palate and part of posterior wall of pharynx covered with an adherent, grayish-white membrane. Swab taken before cleansing showed, besides numerous other bacteria, the presence of the bacillus of diphtheria. Swab taken after brushing with peroxid of hydrogen and then cleansing by gargling with a teaspoonfúl of peroxid in a glass of water showed numerous bacteria, including staphylococci and many bacilli, but none of them would grow.

Case 13.—Pyorrhea alveolaris. Swab taken before cleansing showed, besides large numbers of bacteria, most of which were gas and acid producers, the presence of masses of *Staphylococcus pyogenes albus* which was grown in pure culture. Swab taken after cleansing with lysol showed but very little change except in numbers, the bacteria growing quite as well after the cleansing as before.

Case 14.—Swab taken from a cavity in a carious tooth showed a great mass of bacilli and fungi. On cultivation, the bacilli were found to be composed of masses of the proteus group, of which the *Proteus vulgaris* was isolated and the *Bacillus acidi lactici* obtained in pure culture.

Case 15.—Sarcoma of the lower jaw with very little ulceration. Swab taken before cleansing showed, besides masses of pus cells and epithelium, large amounts of disintegrated tissue, also large quantities of bacteria, staphylococci and streptococci. The two latter seemed, however, to have lost a great deal of their virulence, for the putrefying germs soon outstripped them in growth. Swab taken after imperfect cleansing with a carbolized solution still showed the presence of bacteria of different sizes and kinds, but they would not grow, owing probably to the presence of carbolic acid.

Case 16.—First stage of pyorrhea. The swab taken before cleansing showed considerable blood and enormous masses of bacteria of all descriptions. These included *Staphylococcus pyogenes aureus* and *albus*.

Case 17.—This patient had his lower jaw resected two days previously on account of a sarcoma. Swab taken before cleansing showed masses of pus cells and epithelium, also masses of bacteria of all shapes and sizes, together with long threads of fungi. There were *Staphylococcus pyogenes albus*, also *Micrococcus tetragenus* and *Bacillus pyocyaneus*. A swab was taken after cleansing by rinsing with an antiseptic solution, and showed some diminution in the number of microorganisms.

Case 18.—Same patient. Swab taken before cleansing four days after operation showed about the same condition as previous instance, but the swab taken after thoroughly syringing the mouth with peroxid of hydrogen and then washing out with a normal salt solution showed no visible growths.

A study was then made of the comparative number of bacteria present in healthy mouths before and after different methods of antiseptization.

First.—Thoroughly scrubbing the gums with a stiff brush and warm soap water, afterwards rinsing thoroughly with a normal salt solution and rubbing with a sterile gauze from two to five minutes. This will render the mouth sterile in two out of five cases and will reduce the number of germs in the other mouths from thousands to only a few colonies.

Second.—Rinsing the mouth with mild antiseptics, such as boracic acid, thymol, 30 per cent. solution of alcohol or a weak solution of chloroform. It was found that simply rinsing the mouth had little effect on the bacterial content. This seemed to be due in a large measure to the secretions of the mouth, which come rapidly and neutralize the antiseptic used. If the mouth was first scrubbed well and then an antiseptic used, a practically sterile condition was obtained.

Third.—Disinfectants were next tried and the mouth thoroughly rinsed with either 1 per cent. carbolic acid solution or 1 per cent. solution of formaldehyd or a solution 1 to 10,000 bichlorid. After the rinsing, the mouth was scrubbed, using the normal salt solution, the result was found to be practically the same as in Number 1, that is the mouths were rendered practically sterile.

SUMMARY.

In twenty examinations of clean mouths, the greatest number contained staphylococci, 15 *Micrococcus tetragenus* and 6 sarcinæ; of the bacilli, all shapes and sizes, both motile and non-motile, spore-forming and non-spore-forming, and long and short spirillæ were found. Streptococcus was noted in two cases. *Bacillus subtilis*, *Bacillus acidi lactici* and *Bacillus butyricus* were also found.

In one instance *Bacillus prodigiosus* and in three *Bacillus coli communis* were found. In all the cases large numbers of gas and acid producers were found, also several species which could not be identified. In eight of the cases, the pneumococcus was found.

The study of ordinary kept mouths shows more bacteria than in well kept mouths, the putrefactive microorganisms being especially numerous. In two cases of this group the bacillus of influenza was found.

In the third group, the filthy mouths, are found many pathologic processes. In two there was thrush and the organisms of this disease demonstrated. In these filthy mouths millions of bacteria were present and a large number were virulent. The pneumococcus was found in ten of the thirty cases. In the cavities of teeth large numbers of acid producers as well as a great many putrefying bacteria were found.

In the tobacco chewers' mouths, no new organisms were found. In two special pathologic conditions, the *Staphylococcus pyogenes albus* and *aureus*, and the *Streptococcus pyogenes* were found. The *Micrococcus tetragenus* was frequently present. Acid and gas producers, putrefactive bacteria, sarcinæ and fungi were found. Numerous cocci, the yeast fungus, the bacillus of influenza and Friedlander's bacillus were isolated.

In diphtheria and in consumption the germs of these diseases were shown to be present in the mouth.

From the foregoing experiments, it is apparent that the number of micro-organisms, both pyogenic and pathogenic usually present in even healthy mouths is considerable. While in filthy mouths and in those which are the site of pathogenic processes, the number and variety of micro-organisms are greatly increased.

These experiments, though very incomplete, seem to indicate that mechanical means are most to be relied on in an effort to render the mouth sterile, and that the disinfectants, with a possible exception of peroxid of hydrogen, are of only secondary value.

DISCUSSION.

Dr. J. Marshall, San Francisco, said that those having any experience in handling fractures of the jaw, note that about 90 per cent. of all compound fractures of the jaw suppurate. He has operated on those patients without any more disinfecting than washing out the mouth, but has learned from experience that if the mouth is thoroughly cleansed and all salivary deposit removed, and the mouth thoroughly washed with an antiseptic solution, the appliances put in, followed by antiseptic treatment throughout, it is possible to reduce very materially the number of cases in which there is suppuration after the injury. He performs many operations for fractures of the jaw by suturing the jaw, and when he first began he did it with fear and trembling, thinking that in all probability he would get infection through the openings in the bones for the wire sutures. At first he thought that he had, but later found that the trouble originated before that. In most of these cases the patient is not seen for from a few hours to several days after the injury, and infection has already taken place. In cases lasting but twenty-four hours, he has only had 4 or 5 per cent. following compound fracture. He emphasized the fact that if mouths could be kept absolutely clean, dental caries, pyorrhea, inflammations, gingivitis and stomatitis of any kind would be impossible. He does not think we have yet reached the point where we really understand the value of clean mouths. He thinks that if more time were spent teaching patients the value of prophylaxis more good would be done. The work should be begun with children. It would prevent much trouble later on. In his work in the presidio at San Francisco Dr. Marshall found the mouths of the soldiers in a most horrible condition. He had some placards printed and put up in public places "Clean teeth do not decay," and others, "Do not ask the dentist to treat your teeth until you have brushed them." The difference in the condition of the teeth of those men who were there for some time was surprising. Many of them had never owned a tooth brush. After educating them awhile they came with clean mouths and with less disease.

Dr. G. V. I. Brown, Milwaukee, said that in the first place it is an interesting fact, known perhaps, but not considered sufficiently, that if one had been performing a surgical operation in those several mouths and could not or did not use antiseptics, he would probably, so far as pus germs are concerned, have better results in the dirty mouth than in the clean one. With Dr. Brown it is a grave question sometimes how much or how little good antiseptic measures do. Until someone can demonstrate that it is not valuable to disinfect he, of course, will continue on that line, but if those who have demonstrated that there are properties in this saliva or this mixed secretion that have a beneficial action in health, then of course it must be admitted that by the dilution of that fluid injury is done rather than benefit. Dr. Brown made some tests years ago in the following manner: Taking cultures from mouths that were not disinfected in any way—so-called dirty mouths—he, of course, got a great deal of bacteria. Disinfecting with bichlorid for a considerable time in some instances gave practically no result in cultures taken. Following this a solution of carbolic acid was used, stronger than he should want to use for operative purposes, and some essential oil, and after all this he was able to get growths from cultures taken from the same mouth by scraping away some of the superficial cells; he found living germs underneath. He found that he could get good results by using peroxid of hydrogen, which is also a germicide, but is superficial. By using this and then a germicide, he got better results. Mechanical cleaning, H_2O_2, and then a germicide gives the very best results. It is a foregone conclusion that a state of pure asepsis cannot be reached. Even if it were, at any moment it is likely to be disturbed by secretions of one kind or another. The only thing left to do, therefore, is to use as much mechanical force in cleansing as possible, and then to depend on the frequent use of dilute solutions of antiseptics and germicides.

Dr. M. I. Schamberg, Philadelphia, said that this paper should be a valuable adjunct to medical as well as to dental literature for the reason that it will recall the general surgeon to the urgent need for protecting the patient in laparotomies, brain surgery, etc., from infection from the mouth. Careful operators, who have spent much time in preliminary preparations are frequently seen to stand over a patient with open abdomen and describe the conditions there, and it is quite likely that they frequently cause infections with germs from the mouth.

Dr. M. L. Rhein, New York, said that Dr. Levings' views differ materially from our clinical experience with tobacco mouth. It has always appeared to Dr. Rhein that the consensus of views is that a tobacco mouth, other things being equal, will present a decidedly smaller number of colonies on examination than another mouth. It is known that however sterile the oral cavity is made the durability of that condition is extremely limited. The one practical point to Dr. Rhein has always been that with the average practitioner, whether he be distinctly a stomatologist or a medical man, failure in this respect is due to a lack of cleanliness. The advantage of a method approaching a condition of sterility as closely as possible is of undoubted value, and the whole point resolves itself into a question of time. The practitioner has not the time to devote to this purpose.

Dr. G. V. I. Brown, Milwaukee, declared that the value of experiments with regard to infection from mouths covered with gauze is far reaching. In clinics in some of the best institutions in this country, surgeons and nurses with rubber gloves may be seen and every possible precaution against infection is taken, and the surgeon, perhaps, may have a beard or moustache uncovered; at any rate his mouth has no special cleaning, and yet he will discuss the cause and talk right over the open abdomen. Some surgeons are more particular and do cover their mouths. The piece of gauze already prepared to drop over the mouth is advisable. Dr. Brown covers his face with several thicknesses of gauze. He thinks that this is a very important point and a great credit to the section.

Dr. John Marshall, San Francisco, stated that for the last few years in most of the large hospitals these precautions have been followed, the surgeons covered their mouths not only with one or two thicknesses, but with four or five, particularly when performing laparotomies.

Dr. Vida A. Latham, Chicago, asked Dr. Levings how he overcame the tremendous ingrowth of the sacromycetes group. Dr. Latham has just finished a number of experiments in the oral cavity and said that she has been practically overwhelmed with the yeast growth, and that the yeast organism is a prominent organism in the mouth. She also asked Dr. Levings what position he gives to the *B. coli communis*, and whether he is inclined to class it as an allied form to the streptococcus. It has been shown that the coli communis is allied to the pus group. If this is so, this is a cause of peritonitis, cellulitis, etc.

Dr. H. P. Carlton, San Francisco, asked what is the use of having training schools for dental nurses if there are no medical dentists.

Dr. A. H. Levings stated his belief that the bacteriology of the mouth is better understood, as it should be, by the dentist than by the physician, and that the former is a better judge of the bacteriologic contents of the mouth than are physicians ordinarily. He is not aware of any experiments that bear out the statement that the tobacco mouth has fewer organisms than any other mouth. He believes that these arguments are advanced by persons who use tobacco. He classes *B. coli communis* simply as a pus germ—as a pyogenic germ—one of the germs that are most frequently to be dealt with in the intestinal canal and in the abdomen, and certainly it is largely a pus germ. It is the cause of nearly all the pus abscesses in the abdomen. Dr. Levings has found it in many cases in pure culture in abscesses about the appendix, intestinal canal and gall bladder. The yeast germ, he believes, is not found in sufficient quantity to interfere with investigations. If experiments prove anything, they prove that all mouths are filthy, in the sense that they contain pyogenic or pus-producing micro-organisms. In order to render a mouth reasonably aseptic, it is necessary to do something more than gargle or wash; it must be scrubbed out, and on this point he disagreed with Dr. Brown that after rinsing and gargling the mouth masses of bacteria can be scrubbed off from the gums. These particles of foreign materials containing the micro-organisms must be detached by mechanical means, and after that the mouth can be made aseptic and can be kept practically clean by the use of antiseptics. In the education of the dentist, Dr. Levings believes that there are many branches of medicine which are practically useless, and that the prospective dentist is the only individual to be considered. What is good for the dentist is going to be good for the public. When the dentist is properly educated, he is in a position where he can deal most satisfactorily with the public.

THE ORAL MANIFESTATIONS OF DIABETES MELLITUS.[*]

HERMANN PRINZ, M.D., D.D.S.
ST. LOUIS, MO.

Within the last twenty-five years, a vast amount of literature has been produced concerning the etiology, pathology and therapeutics of pyorrhea alveolaris, and, with it all, to-day we are about as far away from its true etiology as in the days of Celsus, who probably was the first medical writer to call attention to this ailment. To J. M. Riggs of Hartford, Conn., American dentistry is indebted for first calling the attention of the profession to this disease in 1869, although it must have been recognized by him as early as 1844. Rehwinkel is usually quoted as being the first (1877) to use the term pyorrhea alveolaris, a name which he borrowed from Albrecht of Berlin. This term, however, is of French origin and is employed for the first time in an article published by Toirac-Desirabode[1] in 1839, in which he speaks of the disease as *pyorrhea alveolodentaire*. Fauchard, in 1746, described this disease as a "kind of scurvy" and Jourdain (1778) seemed to be of the same opinion, although he more particularly emphasized the fact that a pyogenic destruction of the gingivæ and alveoli is concomitant with the other symptoms. Ever since innumerable names have been suggested by the various writers, usually christening the ailment according to their conception, with the most prominent symptoms, such as "cemento-periostitis" (Magitot), "arthro-dental gingivitis" (Galippe), "gingivitis expulsiva" (Marechal de Calvi), "caries alveolaris" (Essig), "interstitial gingivitis" (Talbot[2]), "*atrophia alveolaris præcox*" (Baume), "phagedenic pericementitis" (Black), "syphilitic locolosis alveolaris" (Curtis), "caries alveolaris idiopathica" (Greve[3]), "caries alveolaris specifica" (Arkoevy[4]), "blennorrhea gingivæ," etc., etc. At the last Union meeting of the American Dental Societies of Europe, held at Basel in December, 1904, W. J. Younker of Paris suggested these two names: "Alveolitis calcophagia" and "alveolitis calcica."

For convenience sake, we may define pyorrhea alveolaris as a chronic destructive inflammation of the pericementum, with more or less necrosis of the alveolus of the affected tooth. The causative factors of the disease, according to Miller, may be classified as follows: Predisposing causes, local disturbances, and bacterial infection. The predisposing causes are such factors which lessen the resistancy of the tissues to injuries, viz.: constitutional or local diseases, metabolic disturbances, tuberculosis, rachitis, scorbutus, syphilis, locomotor ataxia, chronic dyspepsia, malaria, diabetes mellitus, metal intoxications, and other disturbances. Some of these enumerated diseases do not produce definite symptoms in the oral cavity; others, again, manifest themselves in the causation of a distinct form of pyorrhea alveolaris, which, according to some clinicians, is classed as a prodromal sign of the primary disease. This seems to be especially true of diabetes mellitus.

Diabetes mellitus is a disease of impaired nutrition. Faulty metabolism, resulting from the materially reduced power of the body to burn up grape sugar, is the causative factor. Postmortem examination of diabetics usually shows very few or no morbid changes of the organs, with the exception of the brain. The sequence of this inhibition of chemical changes in the body is the presence of sugar in the blood of the diabetic which results from the diminished destruction of the sugar, and, as a consequence of this incomplete oxidation, oxybutyric acid, aceto-acetic acid and acetone are formed, which, with the sugar, are excreted with the urine. The nervous system being the controlling factor of the chemical changes in the muscle tissue, it seems proper to suspect certain disturbances which originate in the central nervous system as the primary factor of diabetes mellitus, the more so as certain pathologic signs point in this direction. The fact is verified by performing the classical experiment of Claude Bernard, which consists in puncturing the floor of the fourth ventricle mid-way between the auditory and the pneumogastric nerves. Thus, an artificial diabetes, which is to say, passage of large quantities of sugar with the urine, is produced which may last for several hours. It is a long and well-known fact that pathologic disturbances of the pancreas are responsible for the production of diabetes; von Mering and Minkowski operated on more than fifty dogs, and, when the complete extirpation of the pancreas had been successfully carried out and the animals had survived more than twenty-four hours, well-marked and severe diabetes was produced. If small pieces of the gland remained, however, no symptoms of diabetes are manifested.

According to our present conception of oral pathology, we may take this axiom for granted: There is no pyorrhea alveolaris without micro-organism. The normal oral cavity is inhabited by a rich flora of bacteria, both pathogenic and non-pathogenic. The great resistancy of the very vascular tissues to injuries holds the bacteria at a rather low ebb of virulence. According to Fluegge, however, the slightest interference with this normal resistancy, for instance, a simple pharyngeal catarrh, affords a ready field of attack and the pathogenic germs become extremely virulent. No specific micro-organism has, so far, been isolated as the true causative factor of pyorrhea alveolaris, although Galippe claims to have found and isolated two organisms. Pyorrhea results from a mixed infection; as shown by Goadby, however, the true pus-producing organism, viz., the staphylococcus aureus and albus are found only in about 10 per cent. of all the bacilli present. As before stated, these micro-organisms must necessarily find a *locus minoris resistentiæ* in the tissues of the oral cavity before they can obtain a firm foothold.

It is a well-known fact that diabetes mellitus lessens the resistancy of all the tissues of the body; diabetic gangrene and a tendency to form carbuncles are ample illustrations of this. So-called dry sockets, viz., ill-healing wounds resulting from the extraction of teeth, are frequently traced to existing diabetes. According to Naunyn, the pronounced tendency to local infection in diabetics may be partly explained by the ever-present sugar in the tissues, thus furnishing rich food to certain forms of schizomycetes. This may help to explain why thrush is so frequently seen in the mouths of diabetics. The best authorities on diabetes mellitus, such men as Kuelz, von Noorden,[5] Frerichs, Bunge,[6] Naunyn, etc., agree that no sugar is found in the saliva; however, a distinct acid reaction is usually observed in the oral fluids. This very acidity, to a large extent, is responsible for the increased sensitiveness about the necks of the teeth, which is usually a forerunner of rapid decay about this region. The circular ligament becomes swelled and livid, it loses its hold on the tooth, and thus opens a ready gateway to the micro-organisms. The formation of pus pockets follows and concomitant destruction of the peridental membrane and necrosis of the alveolus results, with final loss of the tooth. The teeth of the upper arch usually are attacked in this manner prior to the lower teeth.

According to Arkoevy,[4] a distinct separation of the two upper centrals occurs which, as a pathognomic symptom, he has termed *diastema pathologicum*. The articulation of the arch is destroyed, and as a consequence of the force which is produced by the more firmer teeth of the mandible, in their curve of motion against those of the maxilla, the latter readily give and more or less prognatism results. The percussion fremitus of Landgraf,[7] which is observed by placing the finger over the end of the tooth root and tapping the tooth, forms a valuable diagnostic means of determining the progress of destruction of the alveolar plates.

The very rapid formation of calcareous deposits about the necks of the teeth in diabetics is another important diagnostic symptom. This "tartar" is usually of a light yellow color and rather soft to the touch. It is not confined to a group of teeth, but forms indiscriminately all over the crowns. The rapid formation may thus be partly explained: The saturation of the body with acids, according to Naunyn, calls forth an increased neutralization by the alkaline earths of the tissues which are largely held in solution by carbonic acid and poured out by the saliva. The CO_2 becomes liberated in the mouth and the precipitated lime salts are deposited about the teeth. The tongue of the diabetic is usually found thick, of a red color, and coated, showing the imprints of the teeth; the papillæ are enlarged. The mucous lining of the mouth shows a livid color resulting from the hyperacidity of the blood; the mouth is usually extremely dry. The typical odor arising from the breath of the diabetic is an important clinical symptom of the disease and is readily observed by the oral specialists. It is a peculiar chloroform-like odor, resembling somewhat sweet cider. This odor is due to the acetone compounds formed in the body. Of course, the most important diagnostic sign of diabetes is the presence of sugar in the urine.

A few therapeutic suggestions added to the summary of oral symptoms of diabetes mellitus may not be amiss. For general treatment the patient, of course, should be under close observation of the physician. The imbibing of large quantities of alkaline waters, such as Vichy, Carlsbad or Neuenahr, is recommended by the best authorities. Strict dieting is pre-eminent. von Noorden's "oatmeal cure" is much lauded by some clinicians. Very recently O. Conheim published encouraging results obtained by administering an extract of the pancreas; this report, however, is too early and too incomplete to be of practical value. The local therapy is the usual routine treatment, removal of all deposits, destruction of the pus pockets, fixation of the loose teeth, correction of malocclusion, and general prophylaxis. As long as the primary disease is present, however, comparatively little can be expected of the local treatment alone.

IMMUNITY.

CHAPTER XXII.

TYPHOID.

Eberth first saw *Bacillus typhosus* in microscopic preparations of the mesenteric lymph glands and spleen of a typhoid corpse, in 1888. Koch also observed it at about the same time, and stained it in the intestinal wall, spleen, liver and kidney. It was obtained in pure culture by Gaffky in 1884.

The organism is rod-shaped, 0.5 to 0.8 by from 1 to 3 microns in dimensions, with nothing characteristic in its morphology. It possesses from ten to twelve flagellæ situated at the end and on the sides and is actively motile under suitable conditions. It forms no spores, is readily cultivated on many media, in which it sometimes forms long threads, and it is not stained by the method of Gram. The maximum growth occurs at the temperature of the body; growth is practically inhibited at from 9 to 15 degrees C.

Intestinal Groups of Bacilli.

The bacillus is one of the rather numerous "intestinal group" of organisms, certain members of which are similar in morphologic and cultural characteristics, and which can be differentiated only by means of special culture manipulations, by animal experiments, or by the agglutinating and bactericidal action of specific immune serum.[1] Several tests are often necessary for positive differentiation. The typhoid bacillus is a feeble producer of acid and ferments none of the sugars with visible gas formation. The colon bacillus forms acid vigorously and ferments various sugars with the production of gas. The paratyphoid bacilli are very similar to that of typhoid but differ in that they ferment dextrose with the formation of gas. The dysentery bacillus from the culture standpoint is almost identical with the typhoid bacillus, showing only the rather uncertain difference of a terminal alkalinity in milk; even this is not distinctive, because typhoid bacilli are sometimes met which produce a similar reaction. The *Bacillus enteritidis* ferments dextrose with the production of gas. The *Bacillus alcaligenes* always produces an alkaline reaction in milk. These points are mentioned only to illustrate the principles of culture differentiation of organisms which are similar in many respects. Even those which are most similar in culture media can be distinguished by properly performed agglutination or bactericidal tests with the corresponding immune serums. Before bacteriologic tecanic was so well developed at it is to-day, the typhoid bacillus, doubtless, was confused with these organisms in many instances. It is in fact less than five years since the organism of paratyphoid fever was identified as distinct from that of typhoid, in consequence of which the recognition of a new disease was possible.

[7] Landgraf: "Kritische Betrachtungen über Pyorrhoea Alveolaris." Deut. Monat. f. Zahnheilkunde, 1903. "Die Initialsymptome der Alveolarpyorrhea." Ibid., 1905.

[1] Of this group the bacillus of dysentery, paratyphoid bacillus, *Bacillus enteritidis* of Gärtner, colon bacillus and *Bacillus alcaligenes*, in addition to the typhoid bacillus, are the most important because of their similar morphologic and cultural properties and the pathogenicity of certain of them.

Habit of B. Typhosus.

So far as known, the typhoid bacillus does not flourish outside the body and its occurrence in nature is dependent on the distribution of the infected excretions of the diseased. Nevertheless, its resistance is considerable and it remains alive and virulent in water, earth, etc., for varying lengths of time according to the nature of its surroundings. It has been found to live for periods of from 2 to 4 weeks to 2 or 3 months in water, from 3 to 4 months in milk, from 3 to 5 months in surface earth, and from 11 to 16 months in sterilized earth; 100 days in ice, from 12 to 30 days in oysters, from 50 to 80 days when dried on clothing, for 3 months in typhoid feces, for 96 days in the dead body of an experiment animal. Its vitality may be retained for many months in a dried condition. When in water or moist earth which is heavily infected with saprophytic organisms, its life is shortened, and it is killed in a relatively short time in the presence of sunlight.

The organism has been cultivated from the earth and infected water, and from the feces, urine, blood, rose-spots and the various organs of typhoid patients. In many instances in which an epidemic has certainly been caused by an infected water supply attempts to cultivate the bacillus from the water have failed. The organisms may not have been included in the samples which were analyzed, or what is equally probable in certain instances, they have died out in the water by the time the disease was so widespread as to be considered epidemic.

Typhoid Epidemics.

Typhoid fever may become epidemic on a large scale in two ways: First, by water infection and second, by contact infection. When the epidemic has as its source infection of a common water supply there is something characteristic about the explosive-like suddenness with which dozens or even hundreds of individuals are stricken within a comparatively short period. This method of infection concerns large villages and cities, principally, the water for which is commonly taken from streams, small lakes or reservoirs. An ill-constructed out-house, or discharges thrown on the ground in the basin of the stream or reservoir are historic conditions which with the first rain or the melting of the snow have made possible the contamination of the water supply of a community. Miniature epidemics have been caused among groups of families which obtained their water in common from wells which chanced to become infected; in one instance typhoid stools had been thrown on the ground adjacent to the well.

There are authentic examples of limited transmission through milk which had been infected by the use of contaminated water in washing the cans, or by individuals in handling the milk. Fruit and vegetables may be infected by washing with contaminated water. It is strongly suspected that oysters infected from sewage have caused more or less extensive outbreaks of the disease.

An epidemic set in motion by infected drinking water or other means may be aggravated and generally prolonged by the occurrence of contact infections (*indirect contact*). The hands of the nurse, physician or attendant may become contaminated from contact with the stools, urine, soiled linen or skin of the patient, and the organisms, subsequently may be transferred to food, drinking water, or in other accidental ways may reach the mouth. Each new case is a fresh focus from which infection may be carried to others. The chances of milk and food infection become greater as the cases multiply. When the discharges are not disinfected or are improperly disposed of rather extensive soil or house infection may occur and the possibility of direct or indirect transmission by germladen dust becomes of importance. Dust infection from dried urine or feces may occur. Drop infection from urine, water, or the sputum of the patient is theoretically possible but would seem to be of minor significance. Flies may carry the organisms from open vaults or cesspools and deposit them on food or in drinking water. The importance of this has been appreciated in relation to epidemics in military camps. Typhoid bacilli have been cultivated from flies which were taken from the vicinity of infected material.

The Infection Atruni.

The micro-organisms gain access to the body through the lymphoid tissue of the intestinal tract (Peyer's patches and the solitary follicles). Rarely it is possible that other infection atria may be utilized. Primary infection of the lungs through inhalation of infected dust has frequently been mentioned as a possibility, but its occurrence is not definitely established. In this instance a typhoid bacillemia would precede intestinal infection or a condition of typhoid septicemia without intestinal lesions would stand as a possibility. It would seem essential for the occurrence of either of these conditions that some local lesion exist from which organisms could constantly be supplied to the blood. Neufeld doubts the ability of the organism to proliferate in the blood stream as in true septicemia because of the strong bactericidal power of the blood, and considers that infection takes place through the intestines even in cases of "typhoid without intestinal lesions."

Incubation and Variations in Virulence.

The incubation period is subject to considerable variations. In one instance in which 500 persons were exposed to infection from a well 13.5 per cent. developed the disease. Of these, 62 per cent. showed symptoms in from 20 to 25 days, 2 per cent in from 14 to 20 days, and 2 per cent. later than 30 days.

Typhoid bacilli cultivated from different cases vary greatly in their virulence. As previously stated, the pathogenic constituents of the organism reside in the bacterial protoplasm and are not excreted in soluble form. Toxic substances, it is true, may be obtained in solution by the autolytic digestion of cultures, extraction of ground-up organisms, or the cell juice may be obtained under high pressure, but it is currently believed that such preparations represent nothing more than the endotoxin which, through the disintegration of the cells, has gone into solution. Up to the present time, immunization with none of these preparations has resulted in the production of an antitoxic serum of accepted value. Certain French authors speak of a true soluble toxin.

Following the development of intestinal lesions the bacilli reach the circulation by way of the lymphatics, and through the action of the bacterial constituents of the blood (amboceptor-complement complex and possibly leucocytes) they are killed and dissolve in large quantities. It is now generally believed that only through the disintegration of the bacterial cells are their toxic constituents thrown into solution in the body, a condition which is necessary in order that the tissue be injured. Infection of the blood stream with living organisms, in the early stages of the disease and preceding relapses, occurs in such a large percentage of the cases that it has come to be recognized as more or less characteristic.

This promises to be an important point from the standpoint of early diagnosis, for they appear in the blood in ad-

A Point in Diagnosis.

vance of the formation of agglutinins; that is to say, the diagnosis may be established by culture methods before the agglutination reaction can be obtained. From 1 to 5 c.c. of blood are drawn from the median vein of the arm and planted into from 30 to 80 c.c. of suitable bouillon, which is then incubated for twenty-four hours and certain quantities of it plated out, or the bouillon culture may be used direct for the agglutination reaction with a known typhoid serum. Inasmuch as typhoid bacilli when freshly cultivated sometimes resist agglutination, it is necessary to supplant the agglutination reaction by the ordinary cultural tests. After from the tenth to the fourteenth day the organisms are commonly not to be cultivated from the blood; it is not improbable that the bactericidal substances of the blood have so increased by this time that the organisms are killed rapidly after reaching the circulation.

As stated previously, they are also found in the various organs, especially in the lymph glands, spleen and bone-marrow in fatal cases. In from one-fourth to one-third of the cases, in the third week, or during convalescence, the urine becomes more or less heavily infected with the bacilli. They may persist in the urine for many weeks after the subsidence of acute symptoms, with little to call the attention of the patient to the condition. Because of its frequent occurrence during convalescence, the process is not to be considered as one of excretion of the organisms from the circulation, but it seems more likely that they arise from metastatic foci in the kidneys—foci which were deposited perhaps at the time similar metastases occurred in the skin to cause the appearance of the rose spots. (Kanjajeff). More than 100,000,000 bacilli per c.c. may be present. The condition may be accompanied by cystitis, varying in degree from mild to severe.

Localization of the Bacilli.

Neufeld claims that the organisms exist in the tissue fluids of the rose spots, and that if they reached the skin in the first instance as metastases in the blood stream they soon become extravascular. They may be cultivated from the rose spots by inoculating media with scrapings from the surface; it is not necessary that the vessels be injured. The rose spot is due to the congestion of the vessels which surround the focus.

The cultivation of the bacilli from the spleen during life by the aspiration of blood from the organ by means of a syringe is not practiced because of the dangers involved.

The gall bladder is infected with considerable regularity during typhoid, and the organisms may proliferate in this situation for years. It has been suggested that reinfection may be caused by the passage of organisms from the gall bladder to the intestines. Typhoid bacilli have been found imbedded in the nuclei of gallstones.

Pneumonia, which develops as a complication of the disease, is commonly caused by other organisms, occasionally by mixed infection with the typhoid bacillus, and rarely by the latter alone. The organism has been found in the bronchial secretions. Serous or purulent pleuritis may be caused by the typhoid bacillus.

Bone lesions (necrosis, abcesses, periostitis), particularly in the lower extremities or in the vertebræ, occur frequently during convalescence, or rarely one or more years later. They may, but more commonly do not, suppurate. The *"Spondilitis typhosa"* of Quincke is thought to be accompanied by compression of the nerve roots by the serous infiltrate of the periosteum. It is thought that true myelitis may accompany, or follow typhoid, the cause being either toxic, or depending on a previous metastatic infection with the organism. Neuritis although the nervous system is characteristically the seat of is not uncommon. True typhoid meningitis is probably rare, intoxication. The typhoid bacillus is a facultative pyogenic organism and may cause abscesses without the aid of other organisms. In purulent lesions, however, mixed infection with the ordinary pyogenic organisms is commonly found.

From the above it would seem that the lesions which may develop during typhoid to a large extent are dependent on the distribution of the organisms, in contrast to the conditions in diphtheria and tetanus. Nevertheless, it appears that the lymphoid tissue and the central nervous system have a special affinity for the toxic constituents of the organisms. In the beginning, the intestinal infection is rather general, being characterized by diffuse hyperemia, a catarrhal condition of the surface and occasionally by minute hemorrhages into the mucous membrane. Very soon, however, their preference for the lymphoid tissue becomes manifest; that this preference depends on anatomic conditions is perhaps not definitely settled, but seems improbable. The vibrio of the cholera under similar conditions shows no such preference for the lymphoid patches.

(To be continued.)

Clinical Report

RECTO-UTERINE FISTULA.*

L. H. BERND, M.D.

PHILADELPHIA.

Patient.—Mrs. S., aged 33, married, housewife, was referred to me at the Italian Hospital, April 5, 1905, with the following history:

History.—Patient has given birth to eight children, three still living, five miscarriages; otherwise she never had any trouble. Her present trouble started five weeks ago, when she aborted a three months fetus. She was curetted by her family physician at that time.

Examination.—The woman is very pale and thin, complains of headache, backache, and a feeling of uneasiness in the lower part of the pelvis; also of a bloody fetid discharge. The perinneum is lacerated through the external sphincter. She has a slight cystocele and a large rectocele. There was no visible discharge, the patient having taken a douche. A unilateral laceration of the cervix could be felt, and the uterus seemed slightly adherent to the rectum. The fundus was enlarged and soft; the tubes and ovaries were in good shape and not markedly tender. Through the speculum a peculiar blood-stained discharge was seen, which had a putrid odor. Temperature was 99, pulse 88.

Treatment.—The patient was prepared for operation in the usual way. As she was being put on the table the nurse informed me that the fluid from the enema came out through the vagina. Careful search, under ether, elicited no opening between the vagina and rectum. An enema of milk was then given. The milk came out through the cervix. A sound passed into the uterus came in contact with the finger in the rectum through a small opening about a half inch above the internal os. A very gentle curettage was done and the uterus was packed with iodoform gauze. The cervix and perineum were then repaired. The packing was left in forty-eight hours. The bowels were moved on the sixth day by an oil enema. The recovery was uneventful, and the patient menstruated on April 18.

Subsequent History.—June 15, 1905, the patient came in and seemed well, except for an adhesion of the uterus to the rectum. She believed herself pregnant, about two weeks.

Remarks.—The case is rather unique. Rectouterine fistulæ are not mentioned in several of the text-books on gynecology. Guilliam mentions the possibility of such cases.

Carcinoma sometimes causes these fistulæ, also tuberculosis. In this case it was probably due to trauma, and, as the fistula was so low, the danger of infecting the peritoneum was greatly decreased. It is possible that the uterus was adherent from a syphilitic condition and that the curette had slipped through at that point when she was curetted by the family physician. My idea of syphilis in this case is due to her history and the syphilitic condition of one of her children. The husband also has rather a suspicious-looking nose, while he denies most emphatically any disease of that kind. It would be interesting to know the further history of this patient and whether or not the pregnancy continued to term, but she has left Philadelphia and I am unable to secure further data.

INTRACELLULAR FERMENTS AS CATALYZERS.

A new insight has been gained through research in physiologic chemistry in the conception of the catalytic nature of intracellular ferments. By a contact substance chemists understand a substance which, by virtue of its presence (and without itself, or in the form of derivatives, appearing in the end-products of reactions), either initiates chemical reactions which otherwise would not occur (chemical "inoculation" or "infection") or accelerates or retards the speed of spontaneous reactions (catalysis). Thus in inorganic chemistry, as everyone remembers, the mixture of manganese dioxid with potassium chlorate accelerates the rate of oxygen liberation and the presence of platinum quickens the burning of hydrogen gas in oxygen at relatively low temperatures. In organic chemistry, ferrous sulphate, by its presence, hastens the oxidation of glycerin by hydrogen peroxid. These are samples of catalysis. It seems probable that for every chemical reaction substances exist which alter its speed. The search for these catalyzers offers a most inviting field for study.

The exact chemical constitution of the intracellular ferments is not known, but this does not hinder the investigation of their catalytic effect. Indeed, in pure chemistry an exact knowledge of the chemical nature of a catalyzer has rarely thrown any light on the character of a catalytic reaction. That such knowledge may be of great importance later is conceivable, but it need not make us pessimistic because we are now ignorant in this particular respect, and see no likelihood of enlightenment soon; there is enough to do at present in studying the relations of catalytic agents of unknown structure to the reactions they influence.

Physiologic chemists are now busy isolating the intracellular ferments from the cells of various organs. One organ may contain many different ferments; the liver, for example, contains more than a dozen of these substances. On the other hand, the same ferment may be present in many different organs, the same oxidizing ferments (aldehydase, for instance,) have been demonstrated in the lymph glands, spleen, thymus, lungs, brain, adrenals, testicles and kidneys.

The isolation of the ferments is by no means easy. Histologic methods are of no avail for the purpose; it is rather the method of the pharmaceutical chemist which has to be resorted to. Just as the latter, seeking the active principle of a vegetable drug, prepares various "fractions" by precipitation, extraction, etc., and tests each fraction to find out in which the active principle is to be found, so the ferment chemist goes to work with an animal organ which is known to be capable of carrying on a definite chemical operation. Most ferments can be obtained from minced organs by extraction with water, in which they form suspensions or colloidal solutions rather than true solutions. To these aqueous suspensions various precipitating agents are added. One ferment goes down with one kind of precipitate, another with another. No general rule can be predicated for the isolation; the ferment chemist has to try a whole series of reagents until he strikes the right one. After isolating the ferment, its quantitative activity has to be determined, and here the methods of physical chemistry have to be employed. This is why the investigator of ferment activity needs to be familiar with chemical mechanics, chemical statics and chemical kinetics—in other words, with the laws governing the phenomena of equilibrium and the velocity of reactions, and with thermodynamics. The effects of temperature, of poisons, etc., on the ferment follows on the simple study of reaction velocity.

The studies of the ferment chemist promise to be of the greatest significance for physiology and pathology. The whole field of internal assimilation comes within their scope, as do the problems of intermediary metabolism. Moreover, for the pathology of the so-called constitutional diseases and perhaps also for the solution of the problems of immunity, the chemistry of ferments and the study of catalytic reactions hold out great hope. Though the details of the methods are too complex to be grasped, perhaps, by the rank and file of medical men, physicians can not fail to be interested in gaining an intelligent understanding of the main points at issue; they will follow the results of research workers competent to investigate these problems with sympathy and expectation.

THE CAUSE OF WHOOPING COUGH.

The practical application by Widal of the principle that in bacterial diseases substances form in the blood which will agglutinate the bacteria causing the disease has led to important additions to the methods of bacterial diagnosis, and has rendered more certain, in some instances, the association of a given bacterium with a given disease. Notwithstanding the large number of diseases now held to be of bacterial origin, the number in which absolute proof of the relation of a given organism to a given disease has been brought forward is relatively small. If we accept Koch's postulates as a standard, and this is generally done by bacteriologists, there are many diseases now held to be bacterial in which absolute proof of this contention is lacking, and this is particularly the case in human diseases not transmissible to animals. It is just such diseases that the agglutination test is of the greatest value.

Among the diseases long considered bacterial, but never definitely proved to be so is whooping cough. For nearly twenty years various observers have described various bacteria in this condition, and since 1897, when Czeplewski and Hensel, and, independently, Koplik, described small-poled bacilli in the sputum, there has been a very close resemblance among the various organisms described. This latter fact made it appear more probable that the real causal agent had been found than if bacteria differing widely in their characteristics had been observed. Most of the observers, even in recent years, have failed to test the agglutinating power of the patient's blood on the organism which they considered the cause of the disease, and this fault has recently been remedied by Wollstein,[1] who has carefully investigated thirty cases. The studies of Wollstein show that if proper precautions in collecting and washing the sputum are taken the same organism can be isolated from practically all developed cases of whooping cough during the first seven or eight weeks of the disease. Before the whoop appears it may be impossible to isolate the bacteria, but after the diagnosis is no longer in doubt the isolation is not attended with great difficulty. The organism which Dr. Wollstein describes tallies very closely with those observed in recent years by the authors previously mentioned, and various slight discrepancies, hitherto puzzling, are doubtless due to improper technic, to the fact that the organism can only be cultivated on hemoglobin containing media, and to the occasional occurrence of similar organisms in healthy individuals. The pertussis bacillus resembles quite closely the influenza bacillus, though somewhat larger. It shows the same cultural peculiarities, and in agglutination tests there is evidence that the two organisms, while different, belong to the same group.

The association of one organism with whooping cough suggests, of course, the possibility that a serum treatment may be available; in fact, such a treatment has been described. As long ago as 1902 Leuriaux[2] gave an account of the successful treatment of sixty-six patients by an antitoxic serum. In view of the fact that the agglutinating power of the blood of various animals can be increased by inoculation with the pertussis bacillus, a serum therapy would seem to be one of the possibilities of the future.

THE PROTEOLYTIC INTRACELLULAR FERMENTS AND AUTOLYSIS.

It has been known for the last 15 years that animal tissues possess the power to break up the albumin molecule, independently of the action of the pepsin in the gastric juice and of the trypsin of the pancreatic juice. Salkowski, in 1890, proved that certain ferments in the liver and in the muscles, substances which could be extracted with water, are able to split up albumins with formation among other substances, of the two amino-acids—leucin and tyrosin. Salkowski spoke of the process as autodigestion, but the name autolysis, later proposed by Jacoby, is that which has been generally accepted. The latter author has been able to isolate the autolytic ferment by means of fractional outsalting. It has since been shown to exist in a whole series of organs, including the spleen, lymph glands, kidneys, lungs, stomach and thymus.

In order to demonstrate autolysis, the organ need not be washed; if the whole liver, or a portion of it, be removed from the body, under aseptic precautions, and so kept in the thermostat, intense autolysis results. This makes it seem probable that the autolytic ferment exists and is active during life within certain limits. Just what part these proteolytic catalytic agents exercise in intermediary metabolism, however, is not yet known. Proteolytic ferments have also been demonstrated in placental autolysis (Matthes) and in carcinoma tissue (Petry). They are increased in the liver in phosphorus poisoning (Jacoby) and may be responsible for the proteolysis of that organ which gives rise to the appearance of leucin, tyrosin, glycocoll, and phenylalamin, which are now known to be excreted in the urine during phosphorus intoxication. Interesting to clinical men is the fact that the pneumonic exudate, during the stage of resolution, is dissolved up gradually, owing to the action of a proteolytic ferment, resident within the cells themselves. Obviously, therefore, autolysis plays an important rôle in the cure of pneumonia (Müller and Simon). When pus breaks down in abscesses, the disintegration is due there also to an autolytic ferment (achalme).

The proteolysis carried on by these autolytic ferments is a hydrolytic cleavage. The chains of amino-acids of which the albumin molecules are built are split asunder owing to the addition of the constituents of water, a hydrogen atom going to one amino-acid molecule and hydroxyl going to the molecule next adjacent. This mode of digestion resembles what happens when proteids are split by pepsin and trypsin. The processes are not identical, however, whether or not the same ferments which split the albumin molecule into amino-acids can also, under other conditions, synthesize amino-acids into albumin, i. e., whether or not the reaction is reversible, as appears to be the case with lipose, the fat-splitting and fat synthesizing ferment, has not yet been ascertained.

PASSING OF PATHOGNOMONIC SYMPTOMS.

It seems very probable that the feature of the session of the American Medical Association at Portland, for which it will go down into history will be its clearing of the field of medical thought of a good deal of its trust in so-called pathognomonic symptoms. While it has been recognized for many years that the whole clinical picture is much more important than the recognition of any one symptom, however serious or apparently significant, the discussions on heart affections, on nephritis and on stomach diseases at the recent session emphasized the necessity for the clinical investigation of all sides of the pathologic condition present, rather than of any single symptom or even set of symptoms. This is the position that has always been recognized by conservative clinicians as most helpful in every generation. It constitutes the reason why practitioners of wide experience have frequently reechoed the old saw: "It is more important to know what sort of a patient has the disease than what sort of a disease the patient has."

---

[1] Jour. of Exper. Med., vol. iii, No. 4.
[2] La Semaine Médicale, July 16, 1902.

In the discussion on heart disease, the old custom of attributing most cases of cardiac disease to rheumatism and of considering this as a sufficient explanation was called in question in order to insist again on the necessity for studying the various types of so-called acute rheumatism that may be present, especially from the standpoint of the pathologist. The declaration was made that not a few of the affections of the heart valves ordinarily attributed to rheumatism resemble those produced by septic conditions, much more closely than has been imagined. Renewed attention was called to the fact that gonorrheal rheumatism occurs much more frequently than was formerly thought, and that heart complications of this affection are not at all rare. From the standpoint of the clinician, it was emphasized that the surest sign of an affection being simple articular rheumatism is the fact that it leaves no mark in the joints and that as the joint tissues, in certain ways, are the analogues of the heart valves, it would be rather surprising if simple rheumatism produced as many heart complications as has been supposed. When the mark is left on the joints, usually some secondary affection has existed and it is to this that the persistent pathologic sequelæ are to be attributed. To a considerable extent, this same thing would seem to be true of heart affection. The necessity for careful investigation of each individual case so as to determine that no secondary infection has taken place will be the true criterion of progress in our knowledge of rheumatic affections and their complications.

With regard to nephritis, it was shown that the presence of both albumin and casts is not sufficient of itself to make the diagnosis of Bright's disease. Indeed, it is when the kidneys are healthiest, as, for instance, in the athlete—the long distance runner, or the oarsman—that casts are most abundant, if somehow sufficient irritation of the organ be set up in order to produce this reaction. On the other hand, it is when degenerative processes are early and active that albumin is likely to be most abundant. The real diagnosis of Bright's disease can not be made until after the changes in heart and arteries which constitute the danger signals of the affection can be recognized. Albumin and casts, either or both, may be present, under exceptional circumstances, for many years without the prognosis of the case necessarily being unfavorable. It is the whole condition of the individual that must constitute the basis of any proper estimation of the significance of the various symptoms in his particular case.

With regard to gastric diagnosis, practically the same conclusions were suggested as with regard to urinary examinations. A single examination in either case, no matter what its apparent significance, should not be allowed to be the main element in the appreciation of the patient's condition. Variations in gastric chemistry are especially likely to be illusory unless all the clinical symptoms of the case are carefully investigated. In general, supposed pathognomonic symptoms of stomach disturbance were stripped of their conclusive significance and shown to be only aids to diagnosis, some of them not of very great value. Only a careful study of all the pathologic conditions present, even of those quite apart from the stomach itself, serves to show what is the real basis for the symptoms present and what indications for treatment are afforded.

No better lesson could well have been impressed on the general practitioners of this country than this precious one of considering all sides of the clinical problem before coming to diagnostic conclusions. Snap diagnoses may seem very brilliant, but, in most cases, they are almost sure to be wrong, and even under the most favorable circumstances they only too frequently call exaggerated attention to some special feature of the case, and thus preclude proper consideration of complicating circumstances that may be of even more importance for the matter of treatment than the basic conditions so readily recognized. If the Portland session shall have driven home even to some slight degree this invaluable precept of studying each individual patient for himself rather than seeking to find the supposed pathognomonic symptom of his affection, then its effects will be far reaching, even beyond expectation.

THE YELLOW FEVER EPIDEMIC.

During the past week the fever has not spread so rapidly. Up to August 8 the total cases numbered 565 and the deaths 113, a mortality of just 20 per cent. Some new foci have been found in Louisiana outside New Orleans, and there seems to have been some concealment of cases. As appeared probable last week, the business men, acting with the local and state authorities, united in asking the President to direct the United States Public Health and Marine Hospital Service to assume *full control* of the efforts to check the epidemic. The commercial interests of New Orleans readily agreed to contribute the fund needed by the service in order to accomplish the heavy task assigned to it. In New Orleans and Louisiana splendid harmony of medical efforts continues, and the physicians of the rest of the country may well be proud of their fellows in the stricken city. The local profession and health authorities promise full and active co-operation with the federal service, of which Surgeon White is locally in chief command.

Already it is possible for us to speak with the greatest pride of the conduct of the citizens of New Orleans. Never has a community more readily or more generally accepted the advice of scientific physicians. With startling and admirable confidence in the newest teachings of scientific medicine with regard to the causation and mode of propagation of yellow fever, New Orleans has furnished the money and the volunteers necessary to carry on rational methods of exterminating an epidemic. New Orleans certainly has earned the respect of the world. Unfortunately there is a background to afford a contrast, for it could be wished that the same praise had been deserved by the neighboring communities. The profession must blush at the medieval quarantines that in some quarters have been raised against the afflicted city. Medical science yet knocks in vain at some doors, and "man's inhumanity to man" stands black on the pages of our newspapers. Even has it been so bad that medical members of local boards of health have resigned in futile protest against the adoption of brutal and irrational methods. From Mississippi comes tales of physicians forced to deny their diagnosis of fever; and the city council of Gulfport, Miss., as an emergency measure, passed an ordinance subjecting to a fine any physician whose report of a yellow fever case is incorrect. From such an environment the civilization of New Orleans shines out brightly, and we fully believe that in the next few weeks she is destined to give the country a salutary lesson of the success of civilized and scientific methods for exterminating epidemic disease.

THE BRITISH MEDICAL ASSOCIATION TO MEET IN CANADA.

At its recent meeting at Leicester, the British Medical Association accepted an invitation extended by the profession of Toronto to meet in that city in 1906. This will make the second time that the British Medical Association has met on this side of the Atlantic, the previous meeting being held in Montreal in 1897. We congratulate our Canadian brethren on having again succeeded in getting the Association to meet with them, and hope that the coming meeting will prove to be even a greater success than the one held in 1897. Toronto is very close to that imaginary line that separates the United States from Canada—a political and not a scientific line—and we have no doubt the great majority of our English brethren will step across this line and shake hands with us. All who do will certainly be welcome.

SUICIDE STATISTICS.

In *The Spectator* for July 27, 1905, Frederick L. Hoffman, the statistician, writes on "The Suicide Record of 1904." He bases his analysis on official returns from 50 American cities reporting 2,927 suicides in 1904. The rate per 100,000 of population is 19.5, which is the highest since 1890, when this annual tabulation was begun and when the rate was 12.0 per 100,000. The increase has been constant, and Hoffman describes it as one of the most dangerous tendencies in modern American life. The detailed results are mystifying, especially as to geographic distribution. San Francisco holds the "bad eminence" of leader in this race, the rate per 100,000 having been 23.7 in 1890, 49.9 in 1900, and 72.6 in 1904. On the other hand, Chicago in 1904 had a fall in mortality from this cause—20.6, as compared with 23.4, the average of the previous decade. Boston and Brooklyn also show a decrease, while Oakland, Hoboken, St. Louis, Indianapolis, Cincinnati, Orange and Pittsburg show very considerable increases. In New York, Milwaukee, New Orleans, Rochester and Buffalo the rate was stationary or showed only slight increase. Neither size nor climate will consistently explain such discordant facts. In the smaller cities some of the larger jumps in 1904 are probably accidental, and will very likely be compensated for in succeeding years. Hoffman thinks the increasing Jewish element in the population of New York accounts for the absence of an increase in the largest center of population. Despite fluctuations and offsetting conditions, it can not be denied that the figures show a gain in the suicide mortality. Abroad, Paris shows a marked fall in the suicide rate for the decade (in 1894, 42.5; in 1903, 26.7). Berlin holds second place among the world's great cities with a rate that varies little from 27.5 per 100,000, while London maintains a low rate—10.8—with only a slight increasing tendency. Hoffman thinks "we may anticipate a still further increase in the suicide rate of American cities in the near future." Perhaps he is correct in this evil forecast, but the premises for such a conclusion do not appear certain. At least, it may be noted, the figures from Paris show that it is possible for the suicide rate in a large city to reach a maximum point from which for some years there is a steady decline. In the light of so many vigorous efforts as are now in progress to improve the conditions of urban life, let us hope that the near future will witness, at least in some of our American cities, a fall in the suicide rate comparable to that still proceeding in Paris.

IDIOPATHIC RECURRING THROMBOPHLEBITIS

Thrombophlebitis is most commonly due to infective agencies, but cases have been observed in which the condition is attributable to the gouty or arthritic diathesis. In the latter circumstances, the occlusion of the vessel has exhibited a recurring tendency, successive portions of the vein being, in turn, involved in an ascending manner. The lower extremities are generally affected and there is little local and no general reaction. In another group of cases, the lesion develops in the absence of a recognizable etiologic factor, and the tendency has been to consider these cases, also, of gouty or arthritic origin. From this view Dr. John B. Briggs[1] is inclined to dissent, and he reports three cases, together with four from the literature, in which recurring thrombophlebitis occurred without obvious cause. In his opinion, the condition is to be attributed to phlebosclerosis, with the development of parietal thrombosis. In the way of treatment he recommends high ligation of the vein, with the object of eliminating the danger of embolic complication and avoiding protracted rest-treatment.

---

[1] Bull. Johns Hopkins Hospital, June, 1905, p. 207.

Medical News

ILLINOIS.

Measles in Evanston.—Evanston is suffering from an epidemic of measles, of which 200 cases have been reported. The Evanston branch of the Chicago Medical Society has appointed a committee consisting of Drs. Sarah H. Brayton, Henry B. Hemenway and Stephen V. Balderston, to assist the local health department.

Farmers Doped and Duped.—It is reported that about 20 farmers in Lake County have been swindled by an alleged physician, who agreed to cure them of supposedly incurable diseases, and accepted in payment for his services notes payable one year from date. Medicine which was sent could not be taken and in due course the notes were presented for payment.

Personal.—Dr. Theodore A. Johnson, Xenia, has been reappointed sanitary physician of the city.——Dr. John S. Kennelley, Easton, was thrown from his buggy July 27 and fractured his left leg.——Dr. Robert J. Midgley, Wilmington, has started for Europe.——Dr. Richard E. Shurtz, Champaign, assistant surgeon, Ill. N. G., assigned Fourth Infantry, has resigned.

Holds License Law Not Retroactive.—The Appellate Court on August 6 affirmed the decision of the Kankakee County Circuit Court in the case against Dr. P. R. Langdon of practicing medicine without a license, deciding in his favor. State's Attorney Miller declares that the state will take the case up to the Supreme Court. Dr. Langdon declares that he was practicing in this state before the act was passed, in 1899, and therefore was not amenable. The case hinged around the word "begin." The act reads that physicians can not "begin" practicing medicine without first obtaining a license. The Appellate Court holds that the law does not apply to doctors who practiced before the act became a law, and the decision was accordingly handed down in favor of the defendant.

Chicago.

Deaths of the Week.—For the week ended August 5 the mortality was equivalent to an annual rate of 14.85 per 1,000, which contrasts unfavorably with 13.57, the rate for the previous week, and 12.78, the rate for the corresponding week of 1904. Of the 567 deaths, 170 were of infants under one year; 47 of children between one year and five years of age, and 91 were of individuals over 60. Acute intestinal diseases caused 129 deaths; consumption, 71; violence, 42; nephritis and heart diseases, each 38; cancer, 33, and pneumonia, 30.

Personal.—Dr. Wilfred H. Manwaring of Johns Hopkins Medical School, at present fellow of the Rockefeller Institute for Medical Research and assistant in pathology in the University of Chicago, has been appointed head of the new department of pathology and bacteriology in Indiana University, with the rank of associate professor.—Dr. Joseph P. Smyth has been re-elected high medical examiner of the Catholic Order of Foresters.——Dr. C. Hubert Lovewell has been appointed to supervise the inspection of passengers from the infected districts in the South at Cairo.

July Heat Increases Mortality.—July, 1905, failed to make good the promise of the early part of the month to establish a new record of low July mortality. The excessively hot weather from July 16 to 19 inclusive was responsible for an increase of nearly one-half over the mortality rate of the first fifteen days, which was only 11.04, while the rate for the week ended July 22 rose to 16.42 per 1,000. Of the 2,280 deaths 595 were of infants under one year; 211 of children from one year to five years of age, and 343 of aged persons over 60. Acute intestinal diseases caused 424 deaths; consumption, 279; violence, 189; nephritis, 157; heart diseases, 196; cancer, 111, and pneumonia, 126. The mortality for the month was equivalent to an annual rate of 13.48 per 1,000.

KANSAS.

Must Fumigate Schoolhouses.—The State Board of Health has issued an order that every schoolhouse in the state must be fumigated before the opening of the school term in September.

Health Board Elects.—At its annual meeting, June 27, the State Board of Health elected Dr. Joseph B. Carver, Fort Scott, president, and Dr. B. J. Alexander, Hiawatha, vice-president. The secretary, Dr. S. Jay Crumbine, Dodge City, holds over.

Now Has Bulletin.—Volume 1, number 1, of the *Bulletin of the Kansas State Board of Health*, appeared July 1. It is a neat eight-page periodical, and the initial number discusses health; gives the vital statistics for June, and prints an article on "The Disgrace of Typhoid."

State Medical Department Preparations.—A building in Kansas City has been leased for the medical department of the State University and lectures will begin September 6.——Two dispensaries have already been established.——The university has secured the use of St. Joseph's, Bethany, the German and St. Margaret's hospitals for clinical teachings for its students.

New Hospitals.—Larned is to have a new fifteen-room hospital.——The corner-stone of the new Allen County Hospital at Gas City was laid July 4.——The Mennonites are building a new hospital at Newton.——The contract for the erection of the Eleanor Taylor Bell Memorial Hospital Medical Pavilion at Rosedale was let August 1. The building will cost $15,000.——St. Mary's Hospital, Emporia, will build a portion of the structure, which will cost $15,000.

Personal.—Dr. Willard F. Jarrett, Fort Scott, has been appointed a member of the faculty of the medical department of the State University, Rosedale.——The governor has reappointed Drs. Earnest P. Mills, Olathe; Alexander B. Scott, Jetmore, and Jonathan B. Carlile, Leon, members of the State Board of Health.——Dr. Clarence C. Goddard, Leavenworth, has been appointed to the chair of nervous and mental diseases in the State University.——Dr. Frank Eckdall has been appointed local surgeon for the Santa Fe System in Emporia.——Dr. Charles H. Lerrigo has been appointed a member of the State Board of Health, vice Dr. Charles Lowry, deceased.——Dr. Charles S. Newlon, superintendent of the School for Feeble-Minded Youth, Winfield, has been deposed by the State Board of Control, and has been succeeded by W. C. Van Nuys, at present assistant superintendent of the Topeka State Hospital.

MARYLAND.

Personal.—Dr. William S. Welch was elected health officer of Annapolis, July 31.

Smallpox.—Two cases of smallpox are reported in Calvert County, which it is believed originated from Washington.

Hospital for Hagerstown.—The success of the project to establish a hospital at Hagerstown has been assured by the donation of six building lots, valued at $15,000 and a check for $5,000 from a gentleman of Williamsport. A fine property on Potomac Avenue has been secured for the site.

Half a Century in Service.—Dr. Joshua W. Hering, Westminster, celebrates this year the semi-centennial of his professional career. During this period he not only was an active practitioner, but served his state as senator, and as comptroller of the state treasury. He is president of the board of trustees of the Western Medical College, and received the degree of LL.D. from St. John's College in 1900.

Baltimore.

Bequests.—The Home for Incurables has received a bequest of $1,500 and the Church Home and Infirmary one of $1,000 recently.

Personal.—Dr. John C. Hemmeter is at Bedford Springs, Pa.——Dr. Leonard Turlington is at Fair Oaks, Va.——Dr. Isham R. Page is at Northport, Maine.——Dr. Harry E. Peterman is at Grant, Pa.——Dr. Arminius C. Pole is at Chautauqua, N. Y.——Dr. F. Randolph Winslow is in Alaska.——Dr. Eugene Lee Crutchfield underwent successfully an operation for appendicitis at St. Joseph's Hospital, July 31.——Dr. Dudley Williams has returned from Europe.——Dr. E. Jones Williams has been appointed health warden of the First ward, vice Dr. Jesse W. Williams, his son, deceased.

Would Equalize Qualifications.—Dr. David Street, dean of the Baltimore Medical College, calls attention to the need of high schools throughout the state that the youths of the country may enjoy advantages of education equal to those in the city. He demands that the legislature take action on this important matter, which has a practical interest at this time to the medical colleges, in view of the requirement of the Association of American Medical Colleges that, commencing with next session, all matriculants shall have had a four-year high school course. He calculates that the Baltimore schools will lose half their students by the enforcement of this requirement.

NEW JERSEY.

Hospital Open.—The first ward in the Italian Hospital, a Roman Catholic institition in Orange, is now open. The hospital is to be called the Hospital of the Immaculate Conception, and the ward just opened is known as St. Anthony's ward.

Personal.—Dr. Orange H. Adams, Vineland, was taken seriously ill August 1 with congestion of the spine.—Dr. Frank Neal Robinson, a member of the Camden City Council, was the guest of honor at a dinner August 6.——Drs. William Q. Clark and Nelson B. Oliphant, Trenton, are in Vienna.

NEW YORK.

Personal.—Dr. Willis. E. Merriman, Jr., Albany, has been appointed resident physician at the Seton Hospital.——Dr. Frank E. White, senior house physician at Ellis Hospital, Schenectady, has resigned and will practice in the city.

Enforce Ordinance.—In accordance with the edict prohibiting holding of assemblages in Syracuse during the scarlet fever epidemic, the health inspector on July 31 dispersed a crowd of about 700 that had gathered to witness a tent vaudeville show.

To Prosecute Quacks.—The Schuyler County Medical Society recently adopted the following preamble and resolution:

> WHEREAS, Schuyler County, and especially the village of Watkins, have become territory infested by quacks and fakers, who are constantly violating the laws of the state by [illegible] and practicing illegally, and who, by their [illegible] are robbing the unsuspicious, and who, by th[illegible] ness, ignorance and deception are endeavoring to put legal and respectable practitioners in contempt: therefore be it
>
> *Resolved,* That the president of this society appoint two members to act with himself, thereby constituting a committee to be known as the legislative committee, and that they be and hereby are instructed and empowered to prosecute all persons in Schuyler County who violate the laws of the state relative to the practice of medicine and surgery; and it is further resolved that all expenses incurred by said committee shall be paid by the Schuyler County Medical Society.

New York City.

Bogus Doctor Sentenced.—Alfred Meyer has been sentenced to eleven months' imprisonment and a fine of $500, or to serve in prison one day for each dollar not paid for posing as a physician and swindling poor people.

Work for the Winter.—The New York Academy of Medicine has sent a communication to the members requesting that titles of papers to be read during the coming winter be sent to the secretary as soon as possible. It is requested that communications be condensed so that they can be presented in from eight to twelve minutes.

Contagious Diseases.—There were reported to the Sanitary Bureau for the week ended July 29, 342 cases of tuberculosis, with 141 deaths; 274 cases of measles, with 13 deaths; 166 cases of diphtheria, with 13 deaths; 141 cases of typhoid fever, with 18 deaths; 54 cases of scarlet fever, with 4 deaths; 21 cases of cerebrospinal meningitis, with 10 deaths, and 14 cases of varicella.

Death Rate Still High.—The death rate for the week ending July 29 was 20.68 per 1,000, which is more than seven points lower than that of the preceding week. There were 455 deaths, 204 less than the preceding week, and of these 27 were directly due to the heat. The deaths from cerebrospinal meningitis during the week numbered only 10, the lowest number for nearly a year.

The Staten Island Mosquito War.—Dr. Doty expresses himself as very much encouraged by the way in which the people of Staten Island have taken up the mosquito crusade. The appropriation of $17,000 asked for the purpose of draining swamp lands has been granted. Twenty thousand circulars have been sent out explaining the methods of getting rid of mosquitoes and of preventing their incubation.

Fear Typhoid Epidemic.—An increase in the number of typhoid fever cases at Coney Island is causing some apprehension. At least 15 new cases have been reported within the last three weeks. There are at present 8 cases of typhoid at the Coney Island Reception Hospital Dispensary and several cases have been transferred to the Kings County Hospital. The outbreak is attributed to polluted water, improper sewage or impure milk. Coney Island is supplied by the same water mains as supply Bath Beach, where typhoid has assumed unusual proportions since June 1.

City Hospital Plans.—Drawings of the plans for the improvements on North Brother Island have been received by the Board of Health which include an increased acreage of more than one-third. The plans include seven new pavilions, five additional isolation ward buildings, two chapels, a large home for nurses and a large storehouse. These improvements, including enlarging the island, will cost $1,500,000. When these plans are carried out the total capacity of the island will be more than 1,000 patients and the plant will be the most complete in the country. Permission has been obtained from the government to make the proposed fill-in.

The American Medical Special.—This excursion train, which left New York on June 24 and arrived there on August 3, after a tour of the West, is said to be the only excursion train in the history of railroading in this country which has made such a lengthy trip and reached home intact without accidents of any kind. The physicians from Greater New York on this train were Dr. and Mrs. Dexter Ashley, Dr. William Francis Campbell, Dr. John W. Parrish, Dr. and Mrs. L. Grant Baldwin, Dr. Thomas F. Reiley, Dr. E. Franklin Smith, Dr. J. Riddle Goffe, Dr. and Mrs. E. F. Hurd, Dr. and Mrs. John T. Nagle, Mrs. J. E. Houghton and Dr. Frederick Holme Wiggin.

Buffalo.

Fumigating School Books.—Work is now in progress of fumigating all the text books used in the public schools of Buffalo.

Personal.—Dr. Frank W. Hinkle has sailed for England.——Dr. Ludwig Schroeter is in the Thousand Islands.——Dr. Marshall Clinton has returned from a trip up the lakes.——Dr. Dewitt C. Greene has returned from a European trip.

Health Department Evicts.—The Health Department has caused many tenants in tenement houses to vacate for violation of the tenement house ordinances. About fifty families, or more than 200 persons, have been compelled to vacate.

German Hospital Staff.—The medical staff of the German Hospital has elected the following officers: President, Dr. Charles H. W. Auel; vice-president, Dr. Marcello Hartwig; secretary, Dr. Frederick Zingheim, and treasurer, Dr. John G. Meidenbauer. Drs. Wilhelm Gaertner and John V. Woodruff have been elected members of the staff.

The University.—The regular term of the medical department of the University of Buffalo will begin September 2. The following graduates of the class of 1904 have received hospital appointments: Buffalo General Hospital—Drs. Herman D. Andrews, Harry E. Brauer, Stephen M. Hill, Discum C. McKenney, Victor A. Pschellas and William J. Sullivan. Erie County Hospital—Drs. William H. Prudden, Arthur C. Schafer, Joseph A. Peaslee, Carl M. Fiero, Abraham Lande, George B. Jackson, Charles W. Bethune and Norton H. Good. Sisters of Charity Hospital—Drs. John M. Flannery, Eugene R. Luiklaten, George A. Bicker and Edwin Carlton Foster. German Hospital—Dr. Jacob Schwitzer.

Osteopathic Diploma Seller Arrested.—"Dr." John W. Banning, president of the Atlantic School of Osteopathy, has been arrested on the charge of issuing diplomas from the Atlantic School of Osteopathy, situated in Buffalo, without license from the State Board of Regents. This school has been in existence for a number of years and is said to have issued many diplomas. Coincident with the arrest of "Dr." Banning comes the announcement that Fred Williams is suing the school for $10,000 for alleged malpractice. Williams, it is alleged, went to the school last March for osteopathic treatment, being told his hip would be strengthened. Following the treatments an abscess developed which compelled Williams to be confined to bed and only now he can get about with crutches.

PENNSYLVANIA.

Personal.—Dr. Milton C. Dunnick, Stewartstown, has located at Newmarket, Md.

Typhoid Decimates Village.—It is reported that one-tenth of the population of Dundaff, Susquehanna County, is ill with typhoid fever, due to the use of water from contaminated wells.

Change of Staff.—On August 1 Dr. Thomas F. Nason assumed charge of the surgical ward of the McKeesport Hospital, and Drs. F. W. Rudolph, Allegheny; J. B. Fealy, New Philadelphia; W. C. Hiesey, Philadelphia, and George L. Howder, Elizabeth, took their places as house staff of the institution.

Want Record Cleansed.—The Medical Association of Monessen has begun civil proceedings in the courts to show cause why the registration of Samuel, otherwise known as Edward S. and Edward Barnes, should not be stricken from the records. He registered under the act of 1881 and recorded seventeen years of continuous practice from 1871 to 1888, as follows: Sandy Lake, four years; Jackson Township, five years; Sheakleyville, three years, and Stoneboro, five years, all in Mercer County. His registration was a few months previous to his conviction of arson and sentence to imprisonment in the Western penitentiary for nine years. It is the purpose of the association to show that this individual never practiced at these places, that he is a bad character and should be prosecuted to the limit. The physicians of Monessen invite all physicians who know of this man and who can give any evidence or the names of persons who could do so, to communicate with their attorney, A. M. Weyant, at Greensburg, or with the president of the association, Dr. Arthur R. Wilson, Monessen.

Philadelphia.

Personal.—Dr. and Mrs. Howard F. Hansell have gone to Lake Rosseau, Canada.——Dr. Alfred C. Whelen is spending part of August in Canada.——Dr. and Mrs. Thomas J. Orbison sailed for Europe on July 21.——Dr. O. Clayman Campbell sailed for Europe on the *Westernland,* August 5.

Hospital Report.—The report of the German Hospital shows that during the month ending July 20, 261 patients were admitted. Of this number 259 were discharged cured, 20 died and 162 remain at the hospital. During the same time 4,677 were treated in the dispensary, of which 1,298 were new patients, and 864 accidents.

To Protect Infants in Hot Weather.—A pamphlet entitled "Care of the Baby in Hot Weather" has been issued by the Bureau of Health, to be distributed by the assistant medical inspectors. It contains much valuable information for the guidance of mothers in the care of their children during the heated season.

Health Report.—During the week ended August 5 there was reported to the health bureau a total of 43 deaths, being an increase of 6 over those of last week and an increase of 55 as compared with the corresponding week of last year. The principal causes of death were: Typhoid fever, 8; whooping cough, 8; diphtheria, 4; tuberculosis, 52; cancer, 20; apoplexy, 15; heart disease, 34; diseases of arteries, 7; acute respiratory disease, 23; enteritis (under 2 years), 95; enteritis (2 years and over), 10; cirrhosis of liver, 7; appendicitis, 6; Bright's disease, 29; premature births, 14; congenital debility, 19; old age, 9; accidental injuries, 16; marasmus, 19. There were 166 cases of contagious disease reported, with 12 deaths, as compared with 123 cases and 25 deaths for the previous week. One hundred new cases of typhoid fever were reported for the week, as compared with 91 the previous week.

Impure Milk.—A bill was introduced in Common Council August 3, prohibiting the sale of adulterated or impure milk. The measure was referred to the committee on law. For all violations there is provided for the first offense a fine of $50, and for the second offense and subsequent offenses a fine of $100. For the enforcement of the terms of the ordinance an inspector of milk is to be appointed by the director of public safety, with the provision that a report is to be made to the Board of Health, the latter to furnish the newspapers with a full list of milk producers from whom samples have been taken during the previous month, with the results of the analysis and with notes indicating to what extent, if any, such samples were adulterated or otherwise altered or deficient. Four dealers accused of using adulterants in milk or selling skimmed for whole milk, were held under $300 bail each for court, August 4. Dr. Robinson of the Board of Health testified for the state.

Hospital Reports.—During the month of July there were 89 patients admitted to the Polyclinic Hospital; 101 were discharged, and 1,845 cases were treated in the dispensary.——The Presbyterian Hospital admitted 261 patients and discharged 267, 208 remaining August 1; 2,200 were treated in the dispensary.——The Women's Hospital admitted 108 patients and discharged 123, the number remaining August 1 being 76. In the clinics there were treated 521 new and 1,631 old patients, a total of 2,152.——Eighty-seven patients were admitted to the Methodist Hospital, 763 were treated in the dispensary and 2,843 visits were made to the dispensary.——In the Howard Hospital 279 accident cases were treated, 2,930 prescriptions were put up, 849 new dispensary patients treated and 31 admitted to the hospital.——The Medico-Chirurgical Hospital treated 211 house patients, 982 in the accident rooms and 5.117 in the dispensaries.——The German Hospital admitted 125 patients, discharged 110; number remaining, 72; 1.603 cases were treated in the dispensary.——In the Mount Sinai Hospital 3.903 patients were treated in the dispensary, 382 accident cases; admitted to wards, 72; discharged cured, 41; remaining at end of month, 31.——Number of cases admitted to St. Agnes' Hospital, 223; remaining in wards from last month, 99; discharged during month, 129; total number of patients in the hospital, 94; number of ambulance calls, 39; brought by patrol, 59; in the out-patient department there were 596 new cases, 2.122 old cases; radiographs, 15; massage and electricity, 154 cases.

TEXAS.

New College Building Almost Ready.—The new building for the medical department of Southwestern University, Dallas, will be ready for occupancy early in October.

New Officers for Hospital.—The directors of the Physicians' and Surgeons' Hospital, San Antonio, have elected Dr. Frank Paschal, first vice-president, and Dr. John S. Lankford, treasurer.

Many Treated for Rabies.—Dr. Benjamin M. Worsham, Austin, who is in charge of the Pasteur Institute, established a few months ago as an adjunct to the State Lunatic Asylum, reports that he has treated 65 patients, and that the institute has been more than self-supporting. Of the patients treated, 3 were bitten by skunks, one was bitten by a wolf, and the remainder were bitten by dogs rabid or suppposed so to be.

Personal.—Dr. Marvin L. Graves, San Antonio, superintendent of the Southwestern Insane Asylum, has resigned to accept the chair of medicine in the University of Texas, medical department, to succeed Dr. James M. McLaughlin. He has been succeeded by Dr. Thomas O. Maxwell, assistant superintendent of the State Lunatic Asylum, Austin.——Dr. John T. Moore, Galveston, associate professor of medicine in the State University Medical Department, has resigned.——Dr. George H. Prothro, Beaumont, sustained a cerebral hemorrhage July 20 and is in serious condition.

Hospital Notes.—A new hospital is to be erected at Temple by the Santa Fe Hospital Association.——The addition to the hospital at the Confederate Home, Richardson, for which an appropriation of $2,500 was made by the legislature, will soon be ready.——Dr. Leo E. Knopf is about to build a general hospital at Sterling City.——A donation of $5,000 has been received from McKinney for the Baptist Sanitarium, Dallas.——Temple Sanitarium has been incorporated at Temple with a capital stock of $20,000, by Drs. Arthur C. Scott and R. R. White, and F. K. Stroop.

GENERAL.

Yellow Fever Situation in Panama.—It seems to be the opinion of those in authority that the yellow fever situation on the isthmus is considerably ameliorated, and that Panama now needs only drastic sanitary measures.

Administration Buildings to Be at Ancon.—A cable from Panama states that as Ancon is the healthiest spot between Panama and Colon the Isthmian government has decided to construct there the administration buildings and residences for the governor and the employes.

Association of Obstetricians to Meet.—The American Association of Obstetricians and Gynecologists will hold its eighteenth annual meeting at the Hotel Astor, Longacre Square, New York, September 19-21. Dr. Robert T. Morris, 616 Madison avenue, New York, is chairman of the local committee of arrangements and will furnish further information on application.

American Public Health Association.—The thirty-third annual meeting will be held in Boston, Sept. 25-29, 1905. The secretary is Dr. C. O. Probst, Columbus, Ohio. Dr. H. P. Walcott, Cambridge, Mass., is the chairman of the local committee on arrangements. The subjects discussed will include: "Methods of Securing More Uniform Instruction and Co-operation in Health Work," "Water Supply," "Tropical Hygiene," "Porto Rico Anemia," "Yellow Fever," "Diseases Common to Man and Animals," "Military Hygiene," "Quarantine Methods," "Recent Researches in Smallpox," "Modes of Dissemination and Rational Quarantine in Epidemic Cerebrospinal Meningitis," "Disinfection," "Sewage and Waste Disposal," and "Car Sanitation."

American Academy of Ophthalmology and Oto-Laryngology.—The tenth annual meeting of this body will be held in Buffalo, Sept. 14-16, 1905. The secretary is Dr. George F. Suker, 103 State Street, Chicago. The chairman of the committee of arrangements is Dr. Alvin A. Hubbell, 212 Franklin Street, Buffalo, N. Y. Some of the forty-seven papers that are announced are on: "Formalin in Ear, Nose and Throat Practice," "Quinin Amaurosis," "Open Treatment or Dressing After Operation," "Glasses in Railway Service," "Retinal Changes as an Aid to Diagnosis in Vascular Degeneration." "Tubercular Iritis," "Bacteriology of Dendritic Keratitis," "Fallacies." "Radium in Diseases of the Throat." "Hay Fever Heresies," "Mastoid Operations," "Hemorrhage," "Failures in Ophthalmic Practice," "Teaching of Ophthalmology," "Diabetic Myopia," and "Cures of Migraine and Idiopathic Epilepsy by Glasses," etc., by Drs. Stein, Culbertson. Barck. Black, Woodruff. Keiper, Willetts. Freudenthal. Ewing. Stucky, Mayer, *Gould,* Alleman, Weeks and Wood, respectively.

THE YELLOW FEVER SITUATION.

REPORT FROM PRESIDENT OF STATE BOARD OF HEALTH—THE UNITED STATES ASSUMES CHARGE—PUBLIC HEALTH AND MARINE-HOSPITAL CIRCULAR.

Report from President of Louisiana State Board of Health.

In accordance with the request of The Journal, Dr. Edward Souchon, president of the Louisiana State Board of Health, very kindly sends the following report:

"The first intimation received by the health authorities in New Orleans of any case resembling yellow fever was on July 13, when two physicians reported to the president of the State Board of Health and to the city health officer jointly, two cases, one dead that day and the other dying, in which hemorrhagic vomiting, jaundice and uremic convulsions were present. Both cases were from the same locality, near the intersection of Decatur and Ursuline streets, in the second district of the city. In both cases autopsies were peremptorily refused. In the same section of the city, peopled almost exclusively by Italians, four more cases with similar symptoms were discovered within the next four days.

"In the absence of an autopsy it was not possible for the health authorities to make a positive announcement of yellow fever, but on July 18 the president of the State Board of Health informed the state health authorities of Texas, Mississippi and Alabama, and the surgeon-general of the United States Marine-Hospital Service, that cases presenting symptoms of yellow fever had come to his knowledge in New Orleans, and that an autopsy would be held at the first opportunity, also that all proper precautions were being taken. The Public Health Service detailed Surgeon J. H. White, on duty in Mobile, to come to New Orleans, where he arrived in company with Dr. C. A. Mohr, acting state health officer of Alabama, on the morning of July 21. The other states did not send any representatives. The visiting physicians were taken to see the fever patients under treatment, and they pronounced the cases to be clinically yellow fever. On the strength of this decision, which the president of the Louisiana State Board of Health immediately wired to the state health authorities of Texas and Mississippi, those states, following the example of Alabama, declared quarantine against New Orleans on the same evening, July 21. On July 22 an autopsy was secured on a case which died in the Charity Hospital, and in which the findings were positive, though not strongly typical. The interest of the medical profession of New Orleans and of the citizens being intensely aroused, an energetic house-to-house canvass of the affected district was begun. This work was greatly assisted by the co-operation of the Italian consul and certain public-spirited Italian priests and citizens of that nationality.

"Owing to the secretiveness and race prejudice of the people among whom the sickness prevailed, it was extremely difficult to get at the real facts. In some instances doors were found locked and barricaded and had to be broken down, discovering cases which had been concealed. This sanitary crusade caused an exodus of Italians, some of whom made their escape into the neighboring country, where they have developed cases of fever at eight or ten localities. In every instance these cases have been promptly discovered and proper steps taken to prevent the spread of the infection. In New Orleans the disease has been almost exclusively confined to the Italian populace, exceptions being a few people of other nationalities accidentally exposed in the infected district.

"Up to August 3 the record of cases, deaths and new foci has been as follows: Cases of fever, 432; deaths, 84; new sub-foci, 69.

"It is the belief of the Louisiana State Board that the infection was introduced by passengers arriving from Belize, British Honduras, prior to the announcement of fever there, May 24, by the representatives of the United States Public Health Service, up to which time, under clean bills of health issued by the American consuls, more than 200 passengers from Belize and Porto Cortes came through to New Orleans after April 1. Edmond Souchon, M.D.,

"President Louisiana State Board of Health."

Louisiana.

United States Assumes Charge.—On request of the governor of Louisiana that the United States Public Health and Marine-Hospital Service assume charge of the yellow fever situation, the President immediately offered any assistance in the power of the government. He also telegraphed Surgeon-General Wyman asking for a report on what the government might do in addition to what the local authorities were already doing. Surgeon Joseph H. White, who was placed in charge of affairs at New Orleans August 7, outlines his plans for combating the disease as follows:

> Our work will be an enlarged application of the system at present in force—taking the utmost precautions to prevent persons from moving while in a possible incubative stage and infecting new districts; a rigid application of measures destructive to mosquitoes to the whole of any infected vicinity; daily inspection of every person in every house where there has been a case of fever and a duplication in such houses of destructive measures for mosquitoes.

The first eight of the forty surgeons of the Marine-Hospital Service who were assigned to duty in New Orleans are as follows: Passed Assistant Surgeons Rupert Blue, Joseph Greene, John McMullen and Donald H. Currie, Assistant Surgeons William C. Rucker, Steger, Smith and Sweet.

Demand That Militia Be Called.—The State Board of Health on August 8 decided to demand that the governor call out the militia to protect travel through the parishes which have imposed drastic quarantine against New Orleans.

New Orleans.—At a special meeting of the finance committee, August 6, $250,000 was offered to the federal government to be used for labor and supplies by the United States Public Health and Marine-Hospital Service in fighting the epidemic of yellow fever.

Archbishop Chapelle, who has been indefatigable in his work among the yellow fever sufferers, was seized with the disease August 5, but is reported as doing well at last accounts and past the crisis.

The record up to the evening of August 7 was as follows: Total cases to date, 565; total deaths to date, 113; total foci of infection, 97. On August 7 there were 32 new cases, with 8 deaths from 4 new foci of infection. On August 8 there were 60 new cases, with 4 deaths from 17 new sub-foci.

Outside Parishes.—Nineteen cases of fever were found at Patterson, St. Mary's Parish, August 7. Several cases were also found at Sellers, in St. Charles' Parish, 3 cases at Shreveport, with 2 deaths, 2 cases in Bon Ami and 1 in Jefferson Parish.

Telephone Service Suspended.—At Arcadia and Baton Rouge telephone service is reported to be suspended on account of the panic among employes in the country.

Detention Camps.—The camps at Fontainbleau, Slidell and Wyman have been improved and enlarged to accommodate the increased number to be held in quarantine.

Other States.

Alabama.—No other cases have been reported and the one patient at Montgomery is convalescing. The state health officer says that the state law guarantees to fever refugees the right to open windows and to have food and water, and that localities which forbid this are violating the laws.

Illinois.—The secretary of the Board of Health on August 5 issued the following order to local health officials south of a line drawn from Vincennes, Indiana, to East St. Louis:

> The Illinois state board of health urgently requests your co-operation in the enforcement of its order pertaining to refugees from the south. No person from any district in which yellow fever has occurred or may occur in the future should be permitted to be permitted to enter Illinois south of the line above described western railway until ten days after he has left the said district. No person from a state in which yellow fever has occurred should be permitted to enter Illinois south of the line above described unless he presents a certificate of health from national, state or municipal health officers. The conditions in the south call for constant vigilance on the part of local health officials of southern Illinois.

The State Board of Health has ordered a restriction in the issuance of health certificates, which in the future will be issued only to citizens of Illinois or to persons vouched for by citizens of Illinois.

Illinois now has seven inspectors in Cairo, beside the secretary of the State Board of Health and his assistant. Dr. Egan reports that many are applying for health certificates.

Kentucky.—Kentucky will be an open state as far as refugees from the fever districts are concerned. The refugees will be subject to examination, however, and will be detained temporarily in camps near the principal cities and towns.

Mississippi.—In addition to the revenue cutter *Winona*, which is now at Gulfport; the revenue cutters *Forward*, now at Key West; *Hamilton*, now at Tampa, and *Seminole*, now at Wilmington, N. C., have been ordered to Gulfport to aid in the maintenance of the national quarantine.

Missouri.—The quarantine orders issued by the Missouri State Board of Health against districts infected by yellow fever will be enforced along the eastern border of the state as far north as St. Louis, along the entire southern border, and along the western border as far north as Kansas City. The medical inspectors will examine all who enter the state from the South.

The St. Louis Board of Health, beginning August 8, will inspect passengers on trains and steamboats arriving from districts infected by the fever. Provision has been made to care for from 300 to 400 patients at the quarantine station.

New York.—Two members of the crew of the *El Paso*, from New Orleans, were removed to Hoffman's Island, August 5, on account of high temperature.——One member of the crew of the *Ligonier*, from Port Arthur, was removed to Hoffman's Island at the same time for observation.——The man from the *Seguranca*, who was detained at quarantine on suspicion of having yellow fever, is improving, and it is thought that his trouble is nothing more than malarial fever.——One passenger and five of the crew of the *San Jacinto*, from Galveston and Key West, have been transferred to Hoffman's Island for observation.——William B. Smith, a pantryman taken from the steamer *Advance*, from Colon, on August 3 with nine other suspects, died from yellow fever August 6. This is the third case of yellow fever on ships entering New York this year and the second death. There are at present nineteen other persons who are detained because of high temperature.

Pennsylvania.—The British steamship *Barnton*, from Port de Paix, Haiti, for Chester, has arrived at the Delaware breakwater with fifteen of her crew ill with "malarial fever." The ship called at Colon before leaving Port de Paix, and after leaving this port she put into Inagua for medical attendance on account of sickness of two of the crew, who were put off at that place. None of the crew has been removed from the ship and the Marine-Hospital authorities have not disclosed the nature of the disease.

Director Martin, of the Department of Public Health and Charities, Philadelphia, has made arrangements for the establishment of a field hospital in the Thirty-third ward for the treatment of any case of yellow fever that may reach the city. Search has been made along the piers of the river front and among the fruit to see if any *Stegomyia fasciata* could be found. All vessels and those on board are daily investigated by the state and federal officers at the quarantine stations at Marcus Hook and Reedy Island.

The State Quarantine Board met August 4 to take action to prevent yellow fever entering the port of Philadelphia from New Orleans. The meeting was called by Dr. Dixon, state commissioner of health, and one of the objects of the meeting was to prevent cargo from any ship from New Orleans or vicinity from being landed there.

South Carolina.—The mayor of Charleston has proclaimed a quarantine against fever refugees, to take effect August 6.

Tennessee.—The urgent quarantine decided on by the Memphis City Council was put in operation at noon, August 7. Guards were placed in the city and inspectors on every train so that no one can enter the city without a permit from the local board of health.

General.

HOW TO PREVENT YELLOW FEVER.

The Board of Public Health and Marine-Hospital Service on July 31 issued a circular emphasizing the practical bearings of the mosquito theory of the causation of yellow fever. Part of it is as follows:

NO MOSQUITOES, NO YELLOW FEVER.

"The infection of yellow fever is carried by mosquitoes, and by no other means is the infection spread.

"Persons take the disease by being bitten by mosquitoes that have previously bitten a yellow-fever patient.

"The mosquitoes to become infected must bite a yellow-fever patient during the first three days of his attack. These first three days, therefore, are the most important time for preventing the access of mosquitoes to a fever patient.

"It is often difficult to decide during the first three days whether a patient has yellow fever; hence the necessity in threatened communities of placing a mosquito bar immediately around every patient who has fever of any kind, and for three days at least.

FACTS ABOUT SCREENING.

"1. The netting used should have meshes fine enough to prevent the passage of mosquitoes (at least 18 to 20 meshes to the inch).

"2. It is important to screen the windows and doors of the house. It is doubly important to screen the beds of fever patients.

"3. Mosquitoes can bite through mosquito nets when any part of the patient's body is in contact with the netting.

"4. Frequent examinations should be made to see that there are no torn places in the netting or that no mosquitoes have found a lodging inside.

"5. The netting should be well tucked in to keep mosquitoes from entering.

"6. If mosquitoes are found within the netting they should be killed inside and not merely driven or shaken out.

"7. All cases of fever should be promptly reported to the local health officer. Awaiting his arrival they should be covered with a mosquito bar.

FACTS BEARING ON MOSQUITO DESTRUCTION.

"1. Mosquitoes live in the vicinity in which they breed. They do not often fly a long distance.

"2. Mosquitoes breed only in water—usually in artificial collections of fresh water.

"3. The young mosquito, or wriggler, lives in water at least seven to twelve days.

"4. Although the wrigglers live in water, they must come frequently to the surface to breathe.

"5. Coal oil on the surface of the water prevents the wrigglers from breeding.

"6. Destroy the breeding places and you will destroy the mosquitoes.

"7. Empty the water from all tubs, buckets, cans, flowerpots, vases once every forty-eight hours.

"8. Fill or drain all pools, ditches, unfilled postholes, and the like.

"9. Change regularly every day all water needed in chicken coops, kennels, etc.

"10. Treat with oil all standing water which can not be screened or drained (1 ounce of oil will cover 15 square feet of surface). The oil does not affect the water for use if the water is drawn from below.

"11. Where oil is applied to standing water it must be distributed evenly over the surface.

"12. Put fine wire netting over cisterns, wells and tanks of water in everyday use.

"13. Places in which it is undesirable to put oil, such as watering troughs for stock, lily ponds, and so forth, can be kept free from wrigglers by putting in gold fish or minnows.

"14. Clean away all weeds, grass, and bushes about ditches, ponds, and other possible breeding places, since these afford a hiding-place for the mosquitoes.

"15. Clean up vacant lots and back yards of all cans, tins, bottles and rubbish.

"16. First do away with, or treat, all places where mosquitoes are known to breed, and then begin to work on places where they might breed.

"17. Inspect and treat with coal oil gutters, culverts, ditches, manholes, catch basins, etc., along the roadside. Manhole covers should be screened.

"18. Houses should be cleared of mosquitoes by burning 1 pound of insect powder or 2 pounds of sulphur to 1,000 cubic feet of space. The mosquitoes will fall to the floor and should be collected and burned.

"19. Success in mosquito destruction depends on the co-operation of the members of the entire community.

"20. While the infection of yellow fever is carried by a single species of mosquito (the *Stegomyia*), to insure its destruction it is necessary to destroy all mosquitoes.

"In places liable to yellow fever both individuals and communities have an effective method of protecting themselves, as indicated above. Use the mosquito bar at once over all cases of fever until the danger from yellow fever has passed. Destroy all mosquitoes."

Paralysis of Fruit Trade.—Central-American steamers are beginning to go back to New Orleans as the Mississippi ports have instituted a strict quarantine against them, and as edicts have been issued against them forbidding fruit trains to go through Mississippi towns.——The United States Fruit Company has already ordered four of its ships back to New Orleans on account of the increase in rigidity of the regulations at Mobile.

Train Service Suspended.—On account of the yellow fever all passenger trains have been discontinued between New Orleans and Houston, putting an end for the time to all through service on the Southern Pacific system.

Mimic War Ends.—The difficulty between the naval forces of Louisiana and Mississippi culminated on August 5, when the Louisiana naval reserves drove from the Louisiana waters the entire forces of the Mississippi quarantine patrol fleet.

Foreign Experts Are Coming.—Surgeon-Major Ronald Ross, I. M. S. (retired), professor of tropical medicine, and Dr. Rupert W. Boyce, professor of pathology and dean of the School of Tropical Medicine, Liverpool, sail August 12 on the *Campania* for New York, en route to New Orleans.

Suspend Cuban Mails.—The postoffice department wired a general order August 8, suspending the dispatch of mails via New Orleans, for the Canal Zone, Cuba and the Republic of Panama.

CANADA.

British Medical Association Coming to Canada.—The British Medical Association has accepted the invitation of the Canadian Medical Association and the local branch of the B. M. A. in Toronto to meet in Toronto in 1906.

Winnipeg General Hospital.—During the week ending July 22, the total number of patients treated in this hospital, was 311, of whom 186 were men, 98 women and 27 children. In the out-door departments 109 were treated.

Honors for Canadian Medical Men.—Mr. I. H. Cameron, professor of surgery in the University of Toronto, and Dr. Francis J. Shepherd, professor of anatomy in McGill University, attended the centenary of the Royal College of Surgeons of Edinburgh and were honored with the degree of LL.D.

Generous Gift to Toronto Hospital for Sick Children.—Mr. John Ross Robertson, proprietor and publisher of the *Evening Telegram*, Toronto, and founder of the hospital for sick children, has recently made a presentation to the hospital of $75,000 for a nurses' home, which will be erected immediately, on the property to the south of the hospital.

Personal.—Dr. F. F. Wesbrook, professor of bacteriology in the University of Minnesota, has been visiting in Winnipeg. ——Dr. Donald McMaster, Sydney, Australia, sailed for England from Montreal on July 28. He has been inspecting children's hospitals through the United States and Canada, in the interests of the Royal Alexandra Hospital of Sydney, which is to be built in the near future.

British Columbia Medical Association.—The annual meeting of the British Columbia Medical Association was held at Vancouver, B. C., July 18-20. Dr. W. D. Brydone-Jack of that city being the president. Among the many members of the American Medical Association who attended the British Columbia meeting after they had been at the Portland session was the President-elect, Dr. W. J. Mayo of Rochester, Minn., who delivered an address on surgery.

Toronto General Hospital.—The city council of Toronto have approved of a by-law to raise $200,000 for the Toronto General Hospital. There was some opposition to the vote owing to the fact that members of the staffs of other hospitals in Toronto opposed it, taking the ground that such a large sum should be voted on by the rate payers and that the other hospitals should share in the donation.——Dr. J. N. Elliott Brown, Toronto, formerly secretary of the Ontario Medical Association, and for the past six years medical health officer, secretary to the governor and gold secretary at Dawson, has been appointed medical superintendent of the Toronto General Hospital to succeed Dr. Charles O'Reilly. July 27 the trustees, members of the staff and nurses of the institution, were presented to Dr. Brown at an informal reception held for his benefit.

FOREIGN.

Plague in India.—The mortality from plague in India is declining throughout the empire.

Plague in Peru.—Ten cases of plague are reported from Paita, in Northern Peru, with three deaths.

Plague and Variola in Brazil.—According to *Public Health Reports*, bubonic plague and variola have formed a fatal alliance in Rio Grande do Sul.

Plague in Chili.—A cable report from Santiago states that on July 9 a case of plague appeared in Junin, and that a suspicious case occurred July 17 in Antofogasta. July 20 the isolation hospital for plague patients was destroyed by fire.

Plague in Japan.—No additional cases of plague have occurred in Japan (excluding Formosa). The prompt suppression of plague in Kagawa Ken, after the disease had gained such a strong foothold, reflects great credit on the sanitary authorities.

Famine and Cholera in India.—A cable from Madras on July 31, stated that cholera had broken out among the refugees from the famine-stricken districts who have been crowding into the city for weeks. The death rate from cholera is stated to be 89.7 per thousand.

New Morgue for Sydney.—It is reported that in view of the representations made by the Health Board of Sydney, Australia, the government has appropriated $15,000 for the erection of a new morgue. It is intended that the building shall be similar in design to the Paris morgue.

New British Red Cross Society.—Under the auspices of Queen Alexandra a new Red Cross Society has been formed to co-ordinate all those existing societies for the care of the sick and wounded in war. It is hoped that Sir Frederick Treves will consent to preside over the executive council.

International Congress of Criminal Anthropology.—The sixth International Congress of Criminal Anthropology will be held at Turin, April 26, 1906. In connection with the congress there will be an exhibition of instruments and apparatus for the diagnosis of physical malformations favoring or influencing the tendency to crime, as well as the various methods of detecting criminal acts.

Memorial Homage to a Peruvian Confrère.—The *Cronica Medica* of Lima gives a list of ten prizes, ranging from $6 to $20, to be awarded for articles bearing on the scientific work of Dr. Raimondi and his personality. The first four prizes are for works on due "appreciation of his studies in the inorganic world," and the next four for the same for the "organic world," and the other two for "the personality of Raimondi and the transcendency of his work." The jury is a large one and comprises engineers as well as physicians. The books and scientific collections of the "Raimondi museum" are placed at the disposal of the competing authors.

Yellow Fever in Guatemala.—According to a report by Acting Assistant Surgeon Peters of the United States Public Health and Marine-Hospital Service, malaria and yellow fever are the prevailing diseases in Livingston. From July 6 to July 15, 4 cases of yellow fever occurred, one of which terminated fatally. Dr. Peters states that other cases of yellow fever undoubtedly have occurred, but have not been reported. He states that the authorities, while denying that the disease is yellow fever, acknowledge that it is a bad fever and that it kills. At first they fumigated the houses in which these cases occurred, but lately have not been doing so.

A School for Mothers in Madrid.—The *British Medical Journal* states that a school for mothers has been founded in Madrid by the Marquis and Marchioness de Casa-Torre. The medical director is Dr. Ulecia, who has charge of a dispensary for sick and weakly children. He gives regular instruction to mothers, making each case as it presents itself the text of a discourse in simple language on the best manner of feeding and generally caring for the child. All the mothers are present so that all may have the benefit of the demonstration. If sterilized milk is considered necessary, it is supplied; food and clothes are also distributed to deserving cases.

The Munich Medizinische Wochenschrift in Court.—The secretary of a Bavarian medical chamber, Dr. H. Sternfeld, considered that he had a grievance against the *Münchener med. Wochft.* for certain circumstances connected with the publication of the transactions of his medical chamber (Oberbayerische Aerztekammer). He consequently sued the responsible editor for damages, but the suit was dismissed with costs both in the first court and in the court of appeals. The editorial comment on the affair is as follows: "The case is typical of the present state of sentiment among colleagues here in Munich. It shows how, in certain circles, a person will act directly contrary to all considerations of professional amity when it is a question of injuring a colleague who has fallen into private disfavor. Private letters not intended for publication were published abroad and a suit for slander built up on absolutely trivial grounds to injure a colleague who had acted solely in the exercise of his professional duties as editor of the local weekly medical journal."

Sanitary Conditions in the Argentine Republic.—It is stated in *Public Health Reports* that the sanitary conditions in this republic are very bad. During the last month terrible floods have been prevalent in portions of the republic, and many lives have been lost either directly as a result or indirectly as a result of illness among persons temporarily living without any shelter. In addition, the weather there has been very cold and rainy, and with heavy fogs. Many of the people living in the districts lately flooded by the heavy rains are now sufferers from pulmonary affections. This is especially true of the northern portions of the republic. In Santa Fe this state of affairs prevails to such a degree as to suggest the conditions of an epidemic of some serious disease. In Gualeguay the rise on the rivers and streams is of such an extent that the surrounding country is inundated to a distance of 25 kilometers. A dispatch dated July 29 states that by a decree of the executive government most important sanitary works for the betterment of the population have been ordered in the province of Santa Fe.

International Medical Association for the Suppression of War.—One of the first acts of this new society was to pass resolutions congratulating President Roosevelt on his initiative and his efforts to bring "two nations together which have been separated by an abyss growing deeper every day." Other resolutions adopted urged a formal declaration of war as the indispensable preliminary to hostilities. Also that it would be wise and humane to insist on an international control of the manufacture of arms and modern explosives. Also that international problems should henceforth be submitted for solution to two tribunals, an international and a humanitarian tribunal. The first, composed of delegates from the corporations, would pass judgment on the question at stake. The second tribunal would be formed of representatives elected by each nation, and this would decide the questions affecting international and humanitarian laws. As mentioned before in these columns, membership in this international association is restricted to physicians. The central office is 25 rue des Mathurins, Paris. Dr. J. A. Rivere is the president.

Public Manifesto of the Medical Profession in Belgium.—The national federation, which includes most of the medical societies of Belgium, has been moved to action by various grievances against the state, the last straw being the refusal of the government to allow the incorporation of the medical assurance company, as mentioned in The Journal, June 24, page 1996. The federation has now issued a manifesto addressed "to the government, to our fellow-citizens, in the name of the physicians of Belgium." It is published in full in the *Gaz. Méd. Belge*, June 22, with a preamble setting forth that the medical corps has never stinted its devotion to the institutions created in the interests of society. "It is always physicians who devote themselves and their energies and who take the lead in all the crusades against social plagues. The crusade against alcoholism, against tuberculosis and against infant mortality were started by physicians. Defenders of public hygiene, propagandists of all the reforms tending to the amelioration of the race, they have always felt in honor bound to place the interests of the whole above their private interests. But physicians are men, and as such they claim the right to live by their profession and not to be placed—on account of their profession—outside of the common laws framed for the benefit of all." The manifesto then takes up one by one various injustices inflicted on physicians by regulations which exclude them specifically from the rights of other citizens or impose special unremunerated duties on them. One of the eight clauses protests against a regulation, dating from 1903, which permits proprietors and insurance companies to send to the free public hospitals the workingmen injured in their service or insured in the societies. The public hospitals, the manifesto states, are made for the poor, not to relieve insurance companies of caring for their injured policyholders. The physicians of the public hospitals, who generally devote their services almost gratuitously, ought not to be burdened with the unremunerated care of these non-indigent persons. Clause 7 states that the number of unremunerated demands made on the physicians by the state is constantly increasing: declaration of diseases, compiling of statistics, free consultations, etc. The national and local administrations are so accustomed to relying on the devoted services of the medical corps that they never think of paying for any of the labor thus imposed. The medical profession believes that it is the duty of the government to take cognizance, in some way besides by mere platonic compliments, of the work constantly being done by physicians for the general welfare. Three-fourths of the entire burden of caring for the sick poor rests on the shoulders of physicians. The manifesto also refers to the refusal to incorporate *La Médicale*. "This society," it says, "grouped a large number of Belgian physicians, and by its powers and functioning it protected these confrères against the pretensions of ordinary insurance societies, insured them suitable remuneration and insured its policyholders prompt aid, prompt reparation and the free choice of physician. The refusal of the government to permit the incorporation of the society is an injury inflicted on the dignity and prestige of the medical profession and on its legitimate material interests." In conclusion the manifesto reiterates the fact that the physician's career is one of self-sacrifice and devotion. His hours are largely given to the poor and to promote the general welfare. He asks to be accorded the same rights as other citizens, at least. L. Merveille of Chênée, editor of the *Gazette*, is president of the federation, and heads the list of the signers, followed by the seven other officers.

DUBLIN LETTER.

The Irish Medical Association.

The annual meeting of the Irish Medical Association has come and gone, and all who attended it seem to have enjoyed a pleasant social gathering. It was held in famous Killarney, and was favored with good weather, so it was perhaps natural that those present succumbed to the *dolce far niente* influence of the place, and that the business which brought them together was somewhat neglected. Of the work actually done at Killarney there is little to record. It was decided to discontinue the publication of the "Irish Medical Directory," which had brought much discredit on the association. It was decided also to maintain the present standard of salaries in the Poor Law Medical Service in spite of the fact that it is disregarded by members and non-members alike.

The Coombe Hospital.

The annual meeting of the Coombe Hospital was held July 6. In the annual report it is stated that a total of 17,351 patients were treated in the hospital, and that only five deaths had occurred during the year. The maternity department has been much improved, a suitable waiting ward and a labor theatre having been added. The number of students attending the hospital had passed all previous figures, and many former students had returned for second or third periods of work. The number of probationary nurses also remained satisfactory.

The Royal Hospital for Incurables.

The Royal Hospital for Incurables, in existence for more than one hundred and sixty years, made a new move this year in summoning the first annual meeting of its friends and subscribers. The meeting, which was held at the hospital on July 6, was well attended. The report showed that of the 213 beds in the hospital, the average number occupied through the year had been 205. Of these thirty-nine were reserved for consumptive patients, and thirty-two for cancer. The result of the treatment of consumption in the hospital showed that even among the patients classed as incurable, healthy surroundings, careful nursing, and sufficient feeding were able to cause a great improvement in health and a prolongation of life.

Dr. Smyly Knighted.

The King has conferred the honor of knighthood on Dr. William J. Smyly, the well-known gynecologist and obstetrician. Dr. Smyly is an ex-master of the Rotunda Hospital, an ex-president of the British gynecologic society, and one of the leaders of the Dublin School of Midwifery.

Correspondence

Cocain and Adrenalin in Enucleation of the Eye.

Jacksonville, Fla., July 28, 1905.

To the Editor:—Hemorrhage during enucleation of the eye is often annoying from the moment of the first incision into the conjunctiva until the final separation of the globe from its attachment, and during the operation is frequently so profuse that special forceps have been devised for its control. If, as the patient goes under the anesthetic, a few drops of a 4 per cent. solution of cocain be dropped into the eye, followed in about five minutes by a few drops of solution of adrenalin chlorid 1-1000, it will be found that it will be necessary to use only a minimum quantity of the anesthetic, and that a most remarkable contraction of even the deeper blood vessels will occur, making the operation practically bloodless.

C. Drew, M.D.

Expulsion of Placenta Before Birth of Child.

Ladinas, Cal., July 19, 1905.

To the Editor:—In reply to Dr. Butt's question in The Journal, July 1, p. 60, permit me to report a case of twins occuring in my practice in New Mexico. The patient, Mrs. D., Mexican, aged 25, iv-para, was taken in labor 24 hours before I was called. I administered treatment for the uterine inertia present. About five hours later, a healthy child was delivered by the aid of forceps. In about ten minutes, the second child, in the vertex position, was delivered, pushing ahead his own placenta. He was somewhat asphyxiated but was easily revived, and two weeks later was more vigorous than the other. There was no more hemorrhage than in the ordinary normal case. I concluded that the uterus while contracting to expel the first child had loosened the second child's placenta which might have been placed very near the internal os. I have as yet been unable to learn of a living child who, without any serious hemorrhage, was delivered after its own placenta.

N. E. Richardson.

Marriages

Robert H. Goheen, M.D., to Miss Edith Ewing, at Wooster, Ohio.

Harry D. Murdock, M.D., to Miss Cathleen Crugo, Winton, South Dakota.

James L. Reilly, MD., Chicago, to Miss Caroline Lynch of Peru, Ill., July 28.

Isom H. Phipps, M.D., Needham, Ind., to Miss Bertha Mabel Cutsinger, July 21.

Harold S. Warren, M.D., to Miss Mary Patterson of San Francisco, July 23.

William L. Bell, M.D., U. S. Navy, to Miss Frances Thomas of Astoria, Ore., July 24.

Nils P. Hansen, M.D., Oakland, Neb., to Miss Ruby Latta of Tekamah, Neb., July 28.

Edward L. Burke, M.D., Culdesac, Idaho, to Miss Mae Thayer of Lyons, Ore., July 24.

J. Eliot Foltz, M.D., Hutchinson, Kan., to Miss Gertrude Harrison of Topeka, Kan., July 5.

E. E. Martin, M.D., Del Norte, Colo., to Miss Bertha L. Gregoire of De Witt, Iowa, July 7.

Frank M. Gordoy, M.D., Cusseta, Ga., to Mrs. Johnnie G. O'Neal of Columbus, Ga., July 26.

Bertram M. Bernheim, M.D., Louisville, Ky., to Miss Hilda Hess Marcus, at Baltimore, July 26.

Isadore Dyer, M.D., New Orleans, to Miss Mercedes Louise Percival, at New Orleans, July 31.

William Daniel Snively, M.D., Rock Island, Ill., to Miss Mary Willf of Philadelphia, June 21.

Josiah Morris Slemons, M.D., Baltimore, to Miss Annie M. Goodsill, at Plattsburg, N. Y., August 2.

Hamilton K. Derr, M.D., Hagerstown, Md., to Miss Louisa McCoy, at Washington, D. C., August 3.

Walter Eugene Vogt, M.D., to Miss Henrietta Whitney Parker, both of Brooklyn, N. Y., August 2

Halstead S. Hedges, M.D., Charlottesville, Va., to Miss Pernette Spencer, at Keysville, Va., July 26.

Henry W. Howden, M.D., Philadelphia, to Miss Helena Worsley, of South Bethlehem, Pa., March 21.

Walter B. Gossett, M.D., Louisville, Ky., to Miss Pattie Zollman, of New Albany, Ind., at Louisville, July 25.

Deaths

Thomas J. Maxwell, M.D. Medical Department State University of Iowa, Keokuk, 1861, a member of the American Medical Association; sometime president of the Iowa State Medical Society, member of the Military Tract Medical Association, Tri-State Medical Society of Iowa, Illinois and Missouri, Des Moines Valley Medical Association, American Association of Obstetricans and Gynecologists, and American Association of Railway Surgeons; professor of principles and practice of surgery and clinical surgery at Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, and previously professor of state medicine and hygiene, anatomy, and obstetrics and gynecology in the same institution; during the Civil War assistant surgeon of the Third Iowa Volunteer Cavalry and surgeon of the One Hundred and Thirty-Eighth U. S. C. T.; one of the most noted surgeons of the middle west, whose method of treating intracapsular fracture of the femur added prominence to his name; died at his home in Keokuk August 1, from cerebral hemorrhage, after an illness of one week, aged 68.

O. Wellington Archibald, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1871, a member of the American Medical Association and of the Association of Military Surgeons of the United States; formerly acting assistant surgeon, U. S. Army, and superintendent of the Iowa Institution for the Feeble Minded, Glenwood, and the North Dakota Hospital for the Insane, Jamestown; a prominent oculist and aurist of St. Paul, Minn., who had been ill for a few days, fainted while taking a bath, July 28, and drowned, aged 60. The Minnesota State Medical Society and the Ramsey County Medical Society adopted resolutions of eulogy and regret, and Drs. John F. Fulton, Arthur Sweeney, Alexander J. Stone, and William D. Kelly of St. Paul, and Dr. Arthur C. Rogers, Faribault, acted as pallbearers.

James F. McShane, M.D. University of Maryland School of Medicine, Baltimore, 1870; vaccine physician, assistant health commissioner and from 1892 to 1897 health commissioner of Baltimore; associate professor of hygiene at the Baltimore Medical College; a member of the Medical and Chirurgical Faculty of Maryland, died at his home in Baltimore, August 1, from progressive paralysis, after an illness of two years, aged 53.

J. Francis Ross, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868; in 1876 vice-president of the Medical Society of the State of Pennsylvania; for many years assistant medical director of the Pittsburg and Western Railroad; died at his home in Clarion, Pa., July 28, from cerebral hemorrhage, after an invalidism of one year, aged 61.

James Hedenberg, M.D. Castleton (Vt.) Medical College, 1852, a member of the Massachusetts Medical Society and of the Middlesex South District Medical Society, for several years a member of the Medford school board; died at his home in Medford, Mass., from heart disease, July 26, after an illness of two years, aged 74.

Herman J. Schiff, M.D. College of Physicians and Surgeons in the city of New York, 1884, of New York City, member of the state association and county society, visiting surgeon to St. Marks Hospital and Mount Sinai Dispensary, died suddenly at Alexandria Bay, N. Y., July 24, from acute gastritis, aged 42.

Uriah Long, M.D. Bellevue Hospital Medical College, New York City, 1865, three times coroner of Colfax County, Neb., and twice city physician of Schuyler; a member of the state and county medical societies, died at his home in Schuyler, July 16, from cardiac dropsy, after an illness of a year, aged 75.

George W. Wackerhagen, M.D. College of Physicians and Surgeons in the City of New York, 1869, a member of the Medical Society of Kings County, and of the Brooklyn Pathological Society, and ex-president of the Brooklyn Surgical Society, died suddenly at his home in Brooklyn, July 25, aged 59.

Wiliam Henry Ellery Masser, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1880, formerly an officer in the Navy, and later on a practitioner of Los Angeles, Cal., died July 23, at the Good Samaritan Hospital, Sunbury, Pa., from intestinal obstruction, aged 53.

Alexander P. Nelson, M.D. Rush Medical College, Chicago, 1864, assistant surgeon of the Eighty-fourth Illinois Volunteer Infantry during the Civil War, died at his home in Kirkwood, Ill., July 19, from cerebral hemorrhage, after an illness of one day, aged 77.

Alexander T. Mitchell, M.D. University of Virginia Medical Department, Charlottesville, 1894, of Vicksburg, Miss., a surgeon in the navy during the Spanish-American War, died at St. Joseph's Infirmary, Lexington, Ky., July 18, after an illness of two years.

Francis Newton Gibson, M.D. Dartmouth Medical School, Hanover, N. H., 1861, assistant surgeon and surgeon of the Ninth New Hampshire Volunteer Infantry in the Civil War, died at his home in Lincoln, Neb., July 11, after a long Illness, aged 65.

Lewis Lynn McCabe, M.D. St. Louis Medical College, 1872, a member of the staff of Mullanphy Hospital, St. Louis, for twenty-five years, died at that institution July 27, from disease of the stomach after an illness of six years, aged 55.

P. Edward Anderson, M.D. Jefferson Medical College, Philadelphia, 1859, Surgeon of the Third Virginia Cavalry, C. S. A., during the Civil War, formerly of Rodophil, Amelia County, Va., died at his residence in Richmond, July 2, aged 67.

Alva H. Shelton, M.D. Cincinnati College of Medicine and Surgery, 1886, a member of the American Medical Association, died suddenly at his home in Long Beach, Cal., July 25, from cerebral hemorrhage, aged 40.

George M. Schweig, M.D. Bellevue Hospital Medical College, New York City, 1872, for many years in the service of the New York City Board of Health, died at his home in New York City, July 5, from heart disease, aged 63.

William J. McDowell, M.D. University of Maryland School of Medicine, Baltimore, 1874, a member of the Medical and Chirurgical Faculty of Maryland, died at his home in Baltimore from Bright's disease August 3, aged 51.

Jesse W. Williams, M.D. College of Physicians and Surgeons, Baltimore, 1890, a health warden of Baltimore, died at the City Hospital, Baltimore, from typhoid fever, August 1, after an illness of 20 days, aged 28.

Horatio F. Wood, M.D. Kentucky School of Medicine, Louisville, 1884, formerly of Chicago, died from paresis at the Illinois Eastern Hospital for the Insane, August 3, after an illness of four years, aged 43.

Robert A. Hardin, M.D. University of Louisville Medical Department, 1861, of Savannah, Tenn., died suddenly from heart disease July 31, at Elkmont Springs, Tenn., where he was spending the summer.

Palmer W. Roberts, M.D. Howard University Medical Department, Washington, D. C., 1883, of Washington, D. C., died in Garfield Hospital in that city, July 20, after a protracted illness, aged 63.

Robert H. Ramsey, M.D. Jefferson Medical College, Philadelphia, 1897, fell from a window in Clarksburg, W. Va., July 30, sustaining injuries which caused his death a short time after.

Peter Looney, M.D. Transylvania University Medical Department, said to have been the oldest physician in Henry County, Tenn., died at his home in Paris, July 26, aged 83.

Robert Walter Pearce, M.D. University of Louisville (Ky.) Medical Department, 1852, died at his home in Louisville, July 29, from senile debility, after a lingering illness, aged 75.

John M. Edwards, M.D., University of the State of Missouri Medical School, Columbia, 1883, died at his home in Bevier, Mo., July 31, after a brief illness from gastritis, aged 51.

Robert H. Hightower, M.D. University of Louisville Medical department, 1872, of Dublin, Ga., died at Atlanta a few hours after an operation for pyonephrosis, July 22, aged 50.

C. Paul Knight, M.D., Medico-Chirurgical College of Philadelphia, died at his home in Clinton, N. J., from tuberculosis, July 18, after an illness of fifteen months, aged 30.

James F. McDougall, M.D. State Certificate Tennessee, 1889, one of the oldest practitioners of Western Tennessee, died at his home in Savannah, July 15, aged 80.

John C. Mundy, M.D. University of Virginia Medical Department, Charlottesville, 1853, died at his home in Allen's Creek, Va., July 13, from heart disease, aged 75.

Walter S. Hay, M.D. Medical College of the State of South Carolina, Charleston, 1874, of Allendale, S. C., a Confederate veteran, died at Aiken, S. C., July 29.

Isaiah White, M.D. New York University, New York City, 1885, one of the oldest practitioners of Utah, died at his home in Salt Lake City, July 23, aged 77.

Samuel Pagin, M.D. Chicago, 1870, died at his home in Goshen, Ind., from cerebral hemorrhage, July 26 after an illness of four days, aged 76.

John Yauney, M.D. Albany (N. Y.) Medical College, 1857, died at his home in Ephratah, N. Y., July 24, after an illness of one year, aged 77.

George Ayres Hewitt, M.D. Jefferson Medical College, Philadelphia, 1877, of Philadelphia, Pa., died at Cape May, N. J., August 1, aged 57.

William W. Clark, M.D. Albany (N. Y.) Medical College, 1894, was drowned in a creek near his home in Maine, N. Y., July 26, aged 36.

Ferdinand G. Oehme, M.D. University of Leipsig, 1892, formerly of Roseburg, Ore., died at his home in Portland, Ore., July 23, aged 79.

David T. Kyner, M.D. Rush Medical College, Chicago, 1856, died at his home in Blue Mound, Ill., July 23, after a long illness, aged 72.

Wesley Light, M.D. Chicago, 1901, died at his home near Freedom, Ind., July 13, from paralysis, after a long illness.

Book Notices

Atlas and Text-Book of Topographic and Applied Anatomy. By O. Schultze. Edited with Additions by G. D. Stewart, M.D. With 125 Illustrations, 85 in Colors. Cloth. Pp. 189. Price, $5.50 net. Philadelphia: W. B. Saunders & Co. 1905.

In this one work an atlas and a text-book are excellently combined. It treats of the anatomy of the human body in its most practical aspects. The author well understands the method of clinical application of a knowledge of anatomy and the entire book is written with this in mind. The illustrations are exceptionally clear and are of a high order. There are many colored drawings of topographical relations which will be of great value to the general practitioner as well as to the surgeon. The translation is excellent and the American editor has added some instructive cuts.

An Introduction to Chemical Analysis, for Students of Medicine, Pharmacy and Dentistry. By Elbert W. Rockwood, M.D., Ph.D., Professor of Chemistry and Toxicology and Head of the Department of Chemistry in the University of Iowa. Second Revised Edition. Illustrated. Cloth. Pp. 255. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1905.

This work, now in its second edition, has been adopted by the author for his class work, and is designed for students in three branches of medicine, viz.: medical, dental and pharmaceutical. The exercises are interleaved with series of questions suggestive to further reference and study. The reactions are also chosen to illustrate chemical incompatibilities of medicinal substances as well as antidotes for poisons. Testing of water, detection of poisons and blow-pipe analysis are also included.

The Detection of Poisons and Strong Drugs, Including the Quantitative Estimation of Medicinal Principles in Certain Crude Materials. By Dr. Wilhelm Autenrieth, Professor in the University of Freiburg. Authorized Translations from the Third Enlarged German Edition. By William H. Warren, Ph.D., Professor of Chemistry, Medical Department of Washington University, St. Louis, Mo. Seventeen Illustrations. Cloth. Pp. 222. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1905.

This is a translation of the well-known German work and therefore retains the processes of the German Pharmacopeia, which the author suggests may be valuable for comparison with those of the U. S. Pharmacopeia. The distribution and elimination of poisons in the animal body are briefly considered, what organs should be examined, what alteration poison undergoes in metabolism, and in what form it is eliminated. Biologic methods used in detecting arsenic and human blood are also included.

The Influence of Growth on Congenital and Acquired Deformities. By Adoniram Brown Judson, A.M., M.D., Orthopedic Surgeon to the Out-patient Department, New York Hospital, 1878-1903. Profusely Illustrated. Cloth. Pp. 276. Price, $2.00. New York: Wm. Wood & Co. 1905.

This book is a brief review of orthopedic surgery with special consideration of the effect of growth. Dr. Judson quotes Hilton as saying that "repair is but the repetition of growth;" natural or artificial rectified growth may thus be counted on in the child or adolescent to substitute for repair, or to supplement it, in the treatment of orthopedic deformities and diseases. The author does not claim to present matter essentially new; the point of view, however, is new and instructive, and the ordinary features of classical orthopedic surgery are grouped around this center in such a way as to make the book *interesting and useful.*

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

ALLEGED UNSCIENTIFIC STATEMENTS BY PHYSICIANS.

Dr. L. sends us a newspaper clipping which narrates the remarkable case of a woman who had "been sick from stomach trouble three months," and who was relieved during a "coughing fit" of a snake eight inches long. The paper says that "Dr. —— —— is the attending physician. He says Mrs. Smith probably swallowed a snake's egg while drinking water." Our correspondent asks: "Is it not time that such stories should cease? Or at any rate, the time has certainly come when physicians' names should not be published giving credence to such a physiologic impossibility as that of a snake's egg hatching inside a living stomach.

Answer.—It is never safe to charge up against a brother physician anything that a newspaper may charge him with doing or saying until the story has been reliably confirmed. White is often changed to black and yes to no in passing over the gossiping tongues of ignorant persons. On the other hand, in the case our correspondent submits, it might very well be that someone in this way is settling a grudge against the victimized doctor. As newspaper editors and physicians advance in educational attainments such instances will become rarer.

FEES OF ATTENDING PHYSICIAN AND CONSULTANTS WHO OPERATE.

——, August 1, 1905.

To the Editor:—I would like very much to have your decision in the following case: Dr. A. was called to see a case, and after careful examination pronounced it a severe case of appendicitis, and advised immediate operation. The family agreed, but desired consultation. Dr. B. was called in and agreed with the diagnosis. The family, however, insisted that Dr. B. should do the operation. Dr. A. agreed and assisted in the operation. The question now arises, is not Dr. A. entitled to the same compensation as Dr. B., Dr. A. having made the diagnosis and having assisted in the operation, and having treated the case until recovered?

Answer.—This query has to be divided. (1) So far as concerns the relative claims of Dr. A. and Dr. B., misunderstanding and friction can only be avoided by frank agreement, preferably in advance, between the physicians and the person who is to pay the bills. Each such case must be settled on its merits by those interested. In the present instance, if it is the patient who refuses properly to recompense Dr. A., let Dr. A. and Dr. B. together agree on proper fees. and in a friendly way lay the matter before the patient, if need be calling for help from the county medical society. If Dr. B. objects to Dr. A. charging an equal fee an impartial medical arbitrator should be asked to adjudicate the case. It is important to present a united front and to secure a good reasonable compensation for professional services. (2) How nearly equal in a given case shall be the fees of the operating surgeon and of the family physician who makes the diagnosis? Everywhere the profession is wrestling with this problem, but no universally applicable solution has yet been propounded. Perhaps the internist and the surgeon never will quite agree, but for the good of the guild they must seem to. There is a strong and growing sentiment that favors a fee for the family physician commensurate with that of the surgeon whom he calls. A few internists already are able to maintain this position, but the public is not yet generally sympathetic. It is this demand that has led some to adopt that wretched makeshift—the wholly immortal secret division of the surgeon's fee. Direct dealing must and will prevail. Dr. A. and Dr. B. should be members of their county medical society, and they and their society should face the question, deciding on the approximate solution that is locally most applicable.

Association News

Official Minutes of the Sections.

The following are the official minutes of the Section on Stomatology, the Section on Laryngology and Otology, and of the Section on Pharmacology and Therapeutics at the Portland Session, July 11-14, 1905. The minutes of the other sections were printed July 29. The minutes of the House of Delegates and of the General Meetings were printed July 22.

Section on Stomatology.

TUESDAY, JULY 11—AFTERNOON.

The Section was called to order at 2:40 p. m. by the Chairman, Dr. Vida A. Latham, Chicago.

The report of the Secretary was read.

Drs. Marshall and Schamberg [illegible] the places of Drs. Peck and Eames on the [illegible]

The address of the chairman [illegible] Dr. Latham on "The Relationship of the Ora[illegible]d Surgery." Discussed by Drs. Rhein, Tal[illegible] Marshall, Brown and Latham.

The next order was a symposium on dental education. The following papers were read:

"A Common Ground for Medicine and Dentistry," by Frank L. Platt, San Francisco.

"The Physician as a Dentist," by Calvin W. Knowles, San Francisco.

"The Physician's Duty to the Child from a Dental Standpoint," by Alice M. Steeves, Boston.

"The Medical Relations of Certain Conditions of the Mouth," by L. Duncan Bulkley, New York City.

These four papers were discussed by Drs. Latham, Schamberg, Brown and Rhein.

Dr. M. L. Rhein of New York offered resolutions, to be laid before the House of Delegates, as to abolishing the contract surgeon in the Army. (These resolutions appear in full in The Journal, July 22, page 280.)

Dr. Brown moved that the resolutions be concurred in by the Section on Stomatology, and referred to the secretary of the Section to send to the House of Delegates if thought best.

This motion was seconded by Dr. Baldwin and discussed by Drs. Baldwin, Brown, Talbot, Schamberg and Rhein. Carried.

Committee on Nominations was appointed, consisting of Dr. G. V. I. Brown, Dr. M. I. Schamberg and Dr. F. L. Platt, to report Thursday.

WEDNESDAY, JULY 12—AFTERNOON.

Section was called to order at 2:18 p. m. by the chairman.

"Dentistry of To-morrow," by H. P. Carlton, San Francisco.

"What Will Probably Be the Dental Educational Standard for the Coming Decade," by Dr. C. C. Chittenden, Madison, Wis.

These two papers were discussed by Drs. Platt, Rhein, Levings, Schamberg, Brown and Carlton.

"Surgical Bacteriology of the Mouth," by Dr. A. H. Levings, Milwaukee, Wis. Discussed by Drs. Marshall, Brown, Schamberg, Rhein, Latham, Carlton and Levings.

"The Treatment of Suppurative Affections of the Face and Neck, Emanating from the Mouth," by Dr. M. I. Schamberg, Philadelphia. Discussed by Drs. Marshall, Brown, Levings, Rhein, Latham and Schamberg.

"The Etiology of Tooth and Nail Corrugations," by Dr. G. Lenox Curtis, New York. Discussed by Drs. Fletcher, Talbot, Schamberg, Marshall and Curtis.

THURSDAY, JULY 13—MORNING.

The Section was called to order at 10 a. m. by the chairman.

"To What Extent Are Teeth Necessary to the Human Being," by Dr M. H. Fletcher, Cincinnati. Discussed by Drs. Talbot, Platt, Brown, Schamberg, Baldwin, Rhein and Latham.

"Fatal Oral Pathologic Conditions," by Dr. G. V. I. Brown, Milwaukee, Wis.

"Surgical Aspects of Disturbed Dentition of the Third Molar," by Dr. M. L. Rhein, New York City.

These two papers were discussed by Drs. Talbot, Schamberg, Platt, Marshall, Brown and Rhein.

THURSDAY, JULY 13—AFTERNOON.

A paper entitled "The Ossification of the Lower Jaw," by Edward Fawcett, Bristol, England, was read.

On motion a vote of thanks was extended to Dr. Fawcett for his excellent paper.

"Ankylostemiasis and Tongue Pigment," by Dr. T. M. Russell Leonard, Grenada, British West Indies. Discussed by Drs. Latham and Talbot.

"Tooth Genesis in Man," by H. W. Marett Tims, London, Eng.

"The Roentgen Rays in Dentistry," by Dr. M. Kassabian, Philadelphia.

"The Oral Manifestation of Diabetes Mellitus," by Dr. Herman Prinz, St. Louis.

The report of the Committee on Nominations was presented as follows: Chairman, C. F. Allen, Newburgh, N. Y.; vice-chairman, H. P. Carlton, San Francisco; secretary, Eugene S. Talbot, Chicago; member of House of Delegates, A. E. Baldwin, Chicago. On motion the report was adopted.

On motion the Section then adjourned *sine die.*

Section on Laryngology and Otology.

TUESDAY, JULY 11.

The Section was called to order at 2:20 p. m.

Chairman's address, Robert C. Myles, New York.

"The Treatment of Empyemata of the Maxillary Antrum Through the Nose," George L. Richards, Fall River, Mass. Discussed by Drs. Otto T. Freer, Chicago; Frank W. Hilscher, Spokane; G. P. Pond, San Francisco; L. C. Cline, Indianapolis; C. F. Welty, San Francisco; W. S. Anderson, Detroit; S. L. Ledbetter Birmingham; A. G. Greenstreet, Seattle; A. DeVilbiss, Toledo; J. H. Martindale, Los Angeles; Robert C. Myles, New York, and George [illegible]

[illegible] er Intranasal [illegible] rrhages)". [illegible] Discussed [illegible] S. Anderson, [illegible] San Francisco; Frank W. Hilscher, Spokane; A. A. Green, Anniston, Ala.; Otto T. Freer, Chicago; H. Foster, Kansas City; Robert C. Myles, New York, and Kaspar Pischel.

Dr. Kaspar Pischel, San Francisco, moved that the chairmen of the Sections [illegible] yngology and Otology be asked to [illegible] sections so that they will not inter[illegible] that the members may attend both [illegible] conded, and was discussed by Drs [illegible] C. Myles, K. Pischel and L. C. Cli[illegible] on the table.

Dr. George [illegible] presented the following resolution [illegible]

Resolved, That the Section on Laryngology and Otology requests the House of Delegates to make arrangements to have the members of sections present at sessions of the A. M. A. receive the bound volumes of the transactions of their respective sections without the charge of $1.00 heretofore collected, and that said transactions be delivered to such members.

The motion was seconded, unanimously carried and referred to the House of Delegates. (See The Journal, July 22, page 285.)

On motion, it was decided to omit the annual smoker and dinner of the section.

WEDNESDAY, JULY 12—MORNING.

"A Demonstration [illegible] the Window Resection Method of the [illegible] of the Nasal Septum," O. T. Freer, Chi[illegible] W. S. Anderson, Detroit, Mich.; Hill Hastings, Los Angeles; George L. Richards, Fall River, Mass.; George F. Cott, Buffalo, N. Y.; G. P. Pond, San Francisco; L. A. Leland, Boston; A. A. Greene, Anniston, Ala.; A. DeVilbiss, Toledo, Ohio; J. F. Barnhill, Indianapolis; Robert C. Myles, New York, and Dr. Freer.

The Nominating Committee, through Dr. George L. Richards, reported the following nominations: Chairman, O. T. Freer, Chicago; Secretary, W. S. Bryant, New York; Delegate, R. C. Myles, New York.

WEDNESDAY, JULY 12—AFTERNOON.

"The Correction of Saddle Nose by Bone Implantation," Cullen F. Welty, San Francisco. Discussed by Drs. W. S. Anderson, Detroit, Mich.; O. T. Freer, Chicago; Hal Foster, Kansas City, Mo.; W. W. Pennell, Mt. Vernon, Ohio; Robert C. Myles, New York, and Dr. Welty.

"Capital Operations for the Cure of Tinnitus Aurium," W. S. Bryant, New York. Discussed by Dr. J. F. Barnhill, Indianapolis.

"Diagnosis of the Intracranial [illegible] to the Middle Ear Suppurations." John F. [illegible]

"Four Cases of Mastoid [illegible] pening the Antrum; Recovery. A Fifth, Periostitis Only, and a Sixth, Destruction of Inner Table of Skull. George F. Cott, Buffalo.

These two papers were discussed by Drs. George L. Richards, Fall River, Mass.; Hill Hastings, Los Angeles; Cullen F. Welty, San Francisco; A. DeVilbiss, Toledo; Kaspar Pischel, San Francisco; Frank W. Hilscher, Spokane; W. W. Murphy, Los Angeles;

G. P. Pond, San Francisco; L. A. Leland, Boston; S. L. Ledbetter, Birmingham, Ala.; Robert C. Myles, New York, and Drs. Barnhill and Cott.

THURSDAY, JULY 13—MORNING.

"Two Cases of Sinus Thrombosis, with Masked Symptoms; Mastoid Operation; One Death; One Recovery," Hill Hastings, Los Angeles, Cal. Discussed by Drs. George L. Richards, Fall River, Mass.; George F. Cott, Buffalo, N. Y.; Cullen F. Welty, San Francisco; W. H. Roberts, Pasadena, Cal.; H. Stillson, Seattle; L. A. Leland, Boston; W. W. Murphy, Los Angeles; John F. Barnhill, Indianapolis; Robert C. Myles, New York, and Dr. Foster.

"Exhibition of a New [illegible] Straw, Marshfield, Ore. Discussed by [illegible] York; L. C. Cline, Indianapolis, and [illegible]lis.

It was moved by Dr. [illegible] River, Mass., and seconded by Dr. Joh[illegible] that the report of the Committee on Nominations be accepted and acted on by ballot. Carried unanimously. On motion of Dr. A. DeVilbiss, Toledo, and duly seconded, the ballot was cast by Dr. George L. Richards, and the following were declared the officers for the Section for the ensuing year: Chairman, Otto T. Freer, Chicago; Secretary, W. S. Bryant, New York; Executive Committee, George L. Richards, Fall River, Mass.; John F. Barnhill, Indianapolis, and Robert C. Myles, New York.

Section on Pharmacology and Therapeutics.

TUESDAY, JULY 11.—AFTERNOON.

Section called to order at 2:30 p. m. by the Chairman, Dr.. Heinrich Stern, New York City.

The Chairman's Address was read. Discussed by Drs. Cottel, Lewis, Kelly and Stern.

It was announced that Dr. Homer I. Keeney had been appointed by the local committee as the member to look after the comfort of visiting members.

Certificate of credentials was presented from American Pharmaceutical Association.

Drs. William C. Wescott, Atlantic City, N. J., and Charles O. Jones, Osceola, Mo., on application, were elected to membership.

Report of Committee on Proprietary Medicines was read by the Secretary. Discussed by Drs. Waugh, Reilly, Chamberlin and Cottel.

Report of Committee to Aid Postoffice Department in Excluding Objectionable Advertisements was read by the Secretary. Dr. Lewis moved that a committee of three be appointed to consider these reports, to accept them, and to draw up resolutions founded on thei[illegible]mitting them to the Section for approval as [illegible]l carried.

Drs. Lewis, [illegible] were appointed as such a committee.

Dr. Chamberlin offered the following resolution:

Resolved, That Section 1, Chapter 1, Book 1, of the By-Laws, be amended so as to read: "A member in good standing of the association of the state in which he resides, who is not in any manner connected with the business of manufacturing pharmacy, or a medical officer of the U. S. Army, of the U. S. Navy, or of the U. S. Public Health and Marine-Hospital Service, may become a member of the American Medical Association by presenting to the general secretary (1) satisfactory evidence of one of the above qualifications; (2) written application for membership on the prescribed form, and (3) the annual dues."

Dr. Chamberlin moved that the representative of the Section on Pharmacology and Therapeutics in the House of Delegates be directed to offer the resolution at the next meeting of the House of Delegates. Seconded.

After discussion by Drs. Lewis, Frick, and the Secretary, and a few remarks by the Chairman, Dr. Chamberlin withdrew his motion, and after further remarks by the Secretary, requested to have his motion reinstated. No vote was taken, however.

None of the Executive Committee being present. Drs. Waugh, Dickinson and, Reilly were appointed an Executive Committee *pro tem.*

The Secretary offered the following resolution, and moved that the Delegate to the House of Delegates be directed to present it before that body:

Resolved, That Book 4, Chapter 2, Section .12, be amended so as to read: "Before only two (instead of one) sections at any annual session."

Motion seconded and carried.

WEDNESDAY, JULY 12.—MORNING.

The Section was called to order at 9.30.

The Chairman appointed as a Nominating Committee Drs. J. V. Kelly, John T. Nagle and H. E. Lewis.

Dr. Bryant read a paper entitled "Common-sense Nasal Therapeutics." Discussed by Drs. Reilly, Waugh, Lewis and Bryant.

Dr. Daniel R. Brower of Chicago read a paper on "Therapeutics of Neuritis." Discussed by Drs. Stern, Lewis, Jones and Brower.

Dr. Chamberlin moved that the delegate be instructed to work with the utmost earnestness for the restoration of the title of this Section as the Section on Pharmacology and Therapeutics. Seconded by Dr. Waugh. Discussed by the Secretary and the Chairman, after which the motion was put and carried.

Dr. Ashley read a paper entitled "Therapeutics of Flat-foot." Discussed by Drs. Reilly, Brower, Lewis, Abbott, Cottel, Waugh, Foss and Ashley.

Dr. Thomas F. Reilly of New York City read a paper on the "Therapeutics of Lupulin." Discussed by Drs. Abbott, Foss, Waugh, Stern, Hallberg and Reilly.

Dr. William F. Waugh, Chicago, read a paper entitled "Arbutin." Discussed by Drs. Hallberg, Foss, Abbott, Cottel, Stern, and Waugh.

Dr. Waugh took the chair, and Dr. Stern read a paper entitled "Sixteen Years' Experience with Formic Acid as a Therapeutic Agent," which was discussed by Drs. Abbott, Reilly, Hallberg, Waugh, and Stern.

The Secretary announced the meeting this afternoon of the Pharmaceutical Congress at the Lewis and Clark Exposition.

An invitation was read from the British Columbia Medical Association.

The Secretary announced that printed copies of the Transactions of the Section could be procured for $1.00, provided seventy-five were ordered in advance.

THURSDAY, JULY 13.—AFTERNOON.

The session was called to order at 2:30, by Chairman Stern.

The Nominating Committee reported in favor of Dr. Thomas F. Reilly, New York, for Chairman; Dr. William Frick, Kansas City, Mo., Vice-Chairman; Dr. C. S. N. Hallberg, Secretary; Dr. Heinrich Stern, Delegate. Ballots were cast and the nominees elected.

Dr. Albert Schneider, San Francisco, read a paper entitled "Uncertain Origin of Many Drugs." Discussed by Drs. Wahrer, Calvin and McDonnell.

Dr. William M. Searby, San Francisco, read a paper on "The U. S. Pharmacopeia—Its Functions."

Dr. C. S. N. Hallberg, Chicago, read a paper entitled "The U. S. Pharmacopeia—Advance in Pharmacy."

Dr. Chamberlain moved that Dr. Abbott read Dr. Tracy's paper, in Dr. Tracy's unavoidable absence. Dr. Abbott read as requested.

These three papers were discussed by Drs. Chamberlain, Lewis, Calvin, Abbott, Stern, Schneider, Searby, and Hallberg.

Dr. H. E. Lewis read a paper on the "Etiologic and Therapeutic Relation of the Pancreas in the Development of Tuberculosis." Discussed by Drs. Foss, Abbott, Searby, Stern and Lewis.

Report of the Committee on Resolutions was read by Dr. Lewis, who presented resolutions:

Resolved, That it is the sense of the Section on Pharmacology and Therapeutics that all proprietary products should have titles as nearly descriptive as possible of their active constituents or elementary composition; and that, while we deplore the present necessity of trade names and titles, we recognize that the evils of substitution are so prevalent that in the interests of honest progressive pharmacy the use of such names and titles can not be avoided. It is, however, the further opinion of this Section that many, if not all, of the objectionable features of proprietary products can be eliminated, first, by the use in connection with the trade name, of some subtitle which will express in scientific terms the nature and character of its composition; and second, by the use on the label or in the disseminated literature, of a descriptive formula which will exhibit the character and proportions of the active constituents.

WHEREAS, The U. S. Pharmacopeia has established standards of nomenclature and orthography which appeal to science and scientific methods: therefore be it

Resolved, That the Section on Pharmacology and Therapeutics respectfully urges the desirability of the American Medical Association accepting the U. S. Pharmacopeia as the standard of nomenclature and orthography in all its transactions and publications.

WHEREAS, The Postmaster-General of the United States and the Secretary of Agriculture are making laudable efforts to restrict or to exclude all obnoxious, fraudulent and dangerous substances from the United States mail: and

WHEREAS, These efforts are nullified to a certain extent by abstruse or incomplete laws, or misunderstanding in their interpretation; therefore, be it

Resolved, That the Section on Pharmacology and Therapeutics of the American Medical Association extend to the Postmaster-General and the Secretary of Agriculture our sincere appreciation of their efforts in behalf of honest pharmacy and assure them that this Section is in accord with their methods and objects; and be it

Resolved, That the Section on Pharmacology and Therapeutics of the American Medical Association emphasize to our legislators and postoffice authorities the necessity of denying to every fraudulent and dishonest firm the use and privileges of the United States mails in every way and particular; and further be it

Resolved, That the Section on Pharmacology and Therapeutics of the American Medical Association urge on the postoffice authorities the desirability of a proper regulation for the protection of the people which will make necessary the proper and plain labeling of all poisonous tablets, powders or other substances before admitting the same to the privileges of the United States mails.

H. EDWIN LEWIS,
C. S. CHAMBERLIN,
W. F. WAUGH.

Dr. Foss moved that the resolutions presented be adopted.

Discussed by Drs. Abbott, Foss, Lewis, Hallberg.

Motion carried.

Dr. Lewis moved that the Secretary of the Section submit to the Board of Trustees the matter concerning *ovoferrin*, asking them to investigate it and the position of Dr. Robinson with reference to it.

Discussed by Drs. Lewis, Abbott, Chamberlain and Hallberg, and motion carried.

Dr. Foss reported the proceedings of the House of Delegates relating to this Section.

A vote of thanks was extended to the retiring Chairman, Dr. Stern.

PORTLAND REGISTRATION.

List of Members, Associate Members and Guests Who Registered at Portland, Oregon.

The total registration at the Portland session was 1,678. We print below the names and addresses of the members, associate members and guests who registered. The names that are starred are of guests. Preceding the names are two summaries: one giving the registration by states and one by sections. In the latter are mentioned "Miscellaneous, 100." This includes those who have not yet forwarded credentials for membership. These are, therefore, not listed by name and are not counted in the summary by states.

Osgood, C. F., Ogden, Utah.
Pennell, William W., Mt. Vernon, Ohio.
Powers, L. M., Los Angeles, Cal.
Richards, Geo. L., Fall River, Mass.
Rogers, Arthur S., Saginaw, Mich.
Solenberger, Amos R., Colorado Springs, Col.
Welty, Cullin F., San Francisco, Cal.

Section on Pharmacology and Therapeutics.

Beard, T. E., Grant's Pass, Ore.
Bowen, Frederick, Jacksonville, Fla.
Chamberlin, C. S., Cincinnati, Ohio.
Clark, G. H., Waterloo, Iowa.
Coad, N. G. O., Hull, Iowa.
Cottel, Willis I., Portland, Ore.
Dickerson, W. L., St. Louis, Mo.
Fassett, Chas. Wood, St. Joseph, Mo.
Foss, John W., Phoenix, Ariz.
Frick, Wm., Kansas City, Mo.
Hallberg, C. S. N., Chicago, Ill.
Harris, E. Eliot, New York, N. Y.
Jones, Philip Mills, San Francisco, Cal.
Kelly, J. V., Philadelphia, Pa.
Leonard, Edwin, Jr., Jersey City, N. J.
Lewis, H. Edwin, Burlington, Vt.
McNair, William Righter, Glendora, Cal.
Reilly, Thos. F., New York City, N. Y.
Riley, Cassius M., St. Louis, Mo.
Ristine, W. H., Crawfordsville, Ind.
Simmons, George H., Chicago, Ill.
Stern, Heinrich, New York, N. Y.
Walker, A. D., Portland, Ore.
Waugh, Wm. F., Chicago, Ill.
Wheatley, Frank G., North Abington, Mass.
Wilson, L. D., Wheeling, W. Va.

Section on Pathology and Physiology.

Black, Stanley P., Pasadena, Cal.
Brooks, Harriet V. Bills, Saginaw, Mich.
Brubaker, Albert P., Philadelphia, Pa.
Christian, Henry A., Boston, Mass.
Hall, Winfield S., Chicago, Ill.
Kemp, Geo. T., Champaign, Ill.
King, Chas. Lee, Pasadena, Cal.
Knabe, Helene, Indianapolis, Ind.
Krone, Carl R., Oakland, Cal.
McClintock, Chas. T., Detroit, Mich.
McFarland, Joseph, Philadelphia, Pa.
New, Charles F., Indianapolis, Ind.
Nusbaumer, Pauline S., Oakland, Cal.
Raley, Franklin H., Salt Lake City, Utah.
Rosenau, M. J., Washington, D. C.
Ruediger, Gustav F., Chicago, Ill.
Smith, Claude A., Atlanta, Ga.
Wynn, Frank B., Indianapolis, Ind.

The following did not specify any particular Section:

Ainslie, George, Portland, Ore.
Aschenbrenner, C. F. Dysart, Iowa.
Axtell, W. H., Bellingham, Wash.
Avey, O. H., Payette, Idaho.
Barnes, E. W., North Powder, Ore.
Botkin, A. W., Mt. Tabor Sta., Portland, Or.
Bowles, Marion K., Joliet, Ill.
Boyd, J. C., Washington, D. C.
Boyers, J. S., Decatur, Ind.
Brundage, M., Shelley, Idaho.
Carson, N. B., St. Louis, Mo.
Carll, Walter E., Oregon City, Ore.
Cargill, Chauncey W., Mason City, Ill.
Carter, R. H., Victoria B. C.*
Collins, I. S., Burke, Idaho.
Cook, John Wallace, Pendleton, Ind.
Douglas, William, Tacoma, Wash.
Downing, W. L., Moulton, Iowa.
Drew, Geo. E., New Westminster, B. C.*
Edwards, Wm., Bowdle, S. D.
Eldridge, E. F., Grand Junction, Colo.
Equi, Marie D., Portland, Ore.
Ferguson, James B., Olivia, Minn.
Ferguson, E. E., The Dalles, Ore.
Giesy, A. J., Portland, Ore.
Hanson, D. S., Cleveland, Ohio.
Hatchett, John A., El Reno, Okla.
Hines, Chas., Forest Grove, Ore.
Hosmer, A. J., Salt Lake City, Utah.
Hughes, H. A., Phoenix, Ariz.
Jayne, R. A., Springfield, Ore.
Jefferson, G. Orlo, Portland, Ore.
Johnson, J. J., Harrison, Ark.
Keith, L. S., Towanda, Ill.
Kirkpatrick, Wm. D., Bellingham, Wash.
Lane, Harry, Portland, Ore.
Lehnkering, C. F., Darlington, Wis.
Lobdell, Mary J., Beloit, Kan.
Long, John W., Bryan, Ohio.
Manning, John F., Everett, Wash.
Martin, Harry S., Spokane, Wash.
Marsh, R. J.; Portland, Ore.
Matthews, A. Aldridge, Spokane, Wash.
Moody, Chas S., Sand Point, Idaho.
Murray, A. J., Lakeside P. O., Ontario.*
Newcomer, M. V. B., Tipton, Ind.
O'Reilly, Robert W., Washington, D. C.
Parkinson, James H., Sacramento, Cal.
Peavler, G. M., Bristol, Tenn.
Pickel, E. B., Medford, Ore.
Prinzing, Jacob, Ontario, Ore.
Purdue, G. C., Wichita, Kan.
Rankin, Theo. W., Columbus, Ohio.
Saunders, Clark E., Union, Ore.
Seidler, W. J., Newark, N. J.
Skene, William H., Portland, Ore.
Smouse, David W., Des Moines, Iowa.
Spottswood, E. W., Missoula, Mont.
Stevens, J. E., Seattle, Wash.
Stickney, V. H., Dickinson, N. D.
Strickland, Melville Cox, Oregon City, Ore.

Tanquary, J. H., St. Louis, Mo.
Thornton, Edgar H., Portland, Ore.
Thorpe, J. L., Jefferson City, Mo.

Turner, W. K., Seattle, Wash.
Turner, S. T., El Paso, Texas.
Tuthill, J. A., Le Roy, Ill.
Vaughn, J. B., Castlewood, S. D.
Watkins, T. R., Aberdeen, Wash.
Watson, W. C., Lima, Ohio.
Watson, Wm. Newbold, Philadelphia, Pa.
Welch, John Frederick, Quincy, Mass.
Wheeler, C. H., Portland, Ore.
Wiltsie, S. F., Seattle, Wash.
Willson, G. C., Nevada, Mo.
Witherbee, O. O., Los Angeles, Cal.
Wood, C. B., Honolulu, Hawaii.
Wood, J. F., Condon, Ore.
Yerdon, Charles F., Brooklyn, N. Y.
Young, James A., Pearl, Idaho.

NEW MEMBERS.

List of new members of the American Medical Association during the month of July, 1905:

ALABAMA.

Dugan, R. H., Prairie Villa.
Fields, E. T., Ensley.

ARIZONA.

Cassady, D., Bisbee.
Hughes, H. A., Phoenix.
Olcott, A. W., Tucson.

ARKANSAS.

Eastman, E. H., Hot Springs.
Hederick, A. R., Booneville.
Parker, J. L., Snyder.
Sweatland, A. E., Little Rock.
Steed, C. J., Hurricane.

CALIFORNIA.

Avey, J. L., Redlands.
Bryant, E. A., Los Angeles.
Barber, D. C., Los Angeles.
Black, J. A., San Francisco.
Brown, Geo. J., Smith River.
Breneman, J. T., Martinez.
Carlton, H. P., San Francisco.
Clark, Wm. A., San Leandro.
Cunnani, T. E., Ventura.
Crediford, D. B., Rialto.
Campbell, C. G., San Bernardino.
Cox, H. M., San Luis Obispo.
Dial, E. A., Santa Barbara.
Davis, S. F., Pomona.
Hesser, G. T., Folsom City.
Herbert. H., Los Angeles.
Hinkle, B. M., San Francisco.
King, E. D., Ukiah.
Kane, J. M., Oakland.
Kelly, A. S. Oakland.
Majors, E. A., Stoledad.
Milton, J. L., Oakland.
Magee, C. L., Los Angeles.
Meng, J. D., Chico.
Mules, J. H., East Auburn.
Nelson, L., San Francisco.
Nixon, A. W., Los Angeles.
Pond, G. P., San Francisco.
Reed, C. E., Redding.
Ryfkogel, H. A. L., San Francisco.
Richardson, N. E., Salinas.
Schmall, E., San Francisco.
Smyth, M. H., Stockton.
Southworth, M. A., San Jose.
Schlageter, H. J., San Francisco.
Troppmann, C. M., San Francisco.
Walker, J. R., Fresno.

COLORADO.

Bren. M. R., Denver.
Daniels, H. P., Colorado City
Epler, Crum, Pueblo.
Hutchinson, W., Del Agua.
Keeney, M. J., Pueblo.
Phelan, N. J., Denver.
Stubbs, A. L., La Junta.
Shere, O. M., Denver.
Wood, W. H., Greeley.
Wilkinson, W. W., Silverton.

CONNECTICUT.

Heady, E. B., Milford.
Lewis, J. B., Hartford.
Loomis, F. N., Derby.
McCabe, E. M., New Haven.
Smirnow, Louis, Bridgeport.
Streit, George, Middletown.
Witter, Wm., Norwich.
Young, C. B., Middletown.

DISTRICT OF COLUMBIA.

Biscoe, F. L., Washington.
Duffey, H. C., Washington.
Key, Sothoron, Washington.

GEORGIA.

Champion, W. L., Atlanta.

HAWAII.

Day, F. R., Honolulu.
Armitage, Edw., Wailuku, Mani.

IDAHO.

Boyd, T. O., Twin Falls.
Collister, Geo., Boise.
Coultchard, G. H., Idaho Falls.
Clouchek, H. W., Twin Falls.
Gritman, C. L., Moscow.
Hamilton, J. J., Caldwell.
Hall, O. L., Star.
Jordan, M. S., Grand Mound.
Moody, C. S., Sand Point.
Murray, J. H. Nampa.
Phillips, C. C., Lewiston.
Springer, W. D., Boise.

ILLINOIS.

Bailey, C. W., Hebron.
Bailey, G. T., Chicago.
Baldwin, B. H., Chicago.
Burch, G. W., Quincy.
Bussey, G. N., Chicago.
Bell, A., Chicago.
Clune, P. J., Ottawa.
Coone, B., Chicago.
Crowder, T. R., Chicago.
Crouch E. L., Jacksonville.
Conner, E. M., Chicago.
Dagg, T. L., Chicago.
Dicus, G. A., Streator.
Duncan, C. E., Flora.
Foster, T. J., De Soto.
Fiske, D., Chicago.
Gaebler, Arthur, Chicago.
Githens, W. K., Hamilton.
Greig, T. O., Chicago.
Hester, E. E., Paxton.
Hansen, G. H., Chicago.
Harper, J. E., Chicago.
Huey, W. B., Chicago.
Hamilton, J. W., Mt. Vernon.
Hassin, G. B., Chicago.
Frank, I., Chicago.
Kieene. F. R. C., Chicago.
Lemen, H. R., Alton.
Leonard, E. F., Chicago.
Lurie, W. A., Chicago.
Lyon, C. E., Toledo.
MacDowell, E. G., Chicago.
McCornack, E. A., Elgin.
Merkl, E. J., Chicago.
Miller, G. P., Chicago.
Miller, J. E., Pittsfield.
McGuire, J. W., Chicago.
Peter, R., Chicago.
Presler. H. M., Cullom.
Presnell, J. F., Chicago.
Phillips, D. C., Chicago.
Podstata, V. H., Dunning.
Rosenow, E. C., Chicago.
Reid, D. W., Jacksonville.
Rochow, C. J. F., Rock Island.
Remmen, N. E., Chicago.
Rudy, F. T., Champaign.
Vary, W. H., Chicago.
Vaupell, W. R., Chicago.
Washburn, W. E., Kewanee.
Whise, M., Chicago.

INDIANA.

Brill, J. H., Indianapolis.
Black, F. W., Ligonier.
Calvin, J. Carruthers, Ft. Wayne.
Cooper, J. A., Terre Haute.
Daugherty, C. A., South Bend.
Freeland, J. L., Indianapolis.
Hawn, C. E., Little York.
Mattison, J. A., Nat. Mil. Home.
McFarlin, J. T., Williams.
Miller, H. H., Galveston.
Niblack, E. S., Terre Haute.
Ritter, M. T., Angola.
Whitesides, L. L., Franklin.
Westover, R. L., Indianapolis.

IND. TERRITORY.

Looney, R. E., Lindsay.

IOWA.

Burgess, J. A. W., Iowa Falls.
Brubaker, J. F., Hubbard.
Bridgman, J. C., Radcliffe.
Breniman, E. M., Ackley.
Butler, F. P., Whitten.
Bartran, R. T., Albia.
Corbit, A. B., Wyoming.
Caldwell, J. W., Steamboat Rock.
Caldwell, J. Willard, Steamboat Rock.
Conner, F. H., Nevada.
Cronk, C. H., Bloomfield.
Dittmer, H. A., Manchester.
Evans, F. J., Iowa Falls.
Hobson, A. J., Hampton.
Hunter, W. W., Monticello.
Hartman, F. T., Waterloo.
Jones, E. H., Eldora.
Koeneman, E. O., Eldora.
Lowder, Wm., New Providence.
McLaughlin, C. W., Washington.
Miller, J. J., Ackley.
Moore, M. F., Martinsburg.
Mabee, C. O., New Providence.
Marsh, W. E., Eldora.
Morton, L. B., Iowa Falls.
Murphy, F. J., Sioux City.
Pagelson, O. H., Iowa Falls.
Petrovitsky, J. S., Cedar Rapids.
Rabe, F. L., Hubbard.
Roberts, W. P., Cleghorn.
Scarborough, H. V., Grand Junction.
Sanders, W. E., Alta.
Stone, Guy, Keswick.
Sherman, A. M., Grinnell.
Trimble, C. S., Buckeye.
Underwood, R. B., Eldora.
Vroom, C. W., Ackley.
Wood, P. R., Marshalltown.
Walker, J. R., Ft. Madison.
Whitney, W. E., Eldora.
Willett, C. C., Whitten.
Wray, C. M., Lawton.
White, E. E., Huxley.

KANSAS.

Boss, J. H., Weir City.
Buley, D. G., Valley Center.
Blades, S. T., Scottsville.
Chadwick, I. B., Tyro.
Fabrigur, A. H., Wichita.
Holt, T. T., Geudo Springs.
Hartwell, G. N., Jamestown.
Hardesty, H. O.,Jennings.
Humfreville, D. W., Waterville.
McManis, J. E., Havensville.
Nichols, S., Herington.
Nye, W. W., Hiawatha.
Shelton, F. W., Independence.
Snyder, H. G., Seneca.
Spitler, S. W., Wellington.
Shannon, L. W., Hiawatha.
Ullman, J. F., Simpson.
Wilson, W. P., Westmoreland.

KENTUCKY.

Hendon, G. A., Louisville.
Lex, E. A., Louisville.
Mosely, J. C., Henderson.
Price, A. D., Harrodsburg.

LOUISIANA.

Burley, C. H., Monterey.
Feucht, E. P., Laplace.

MAINE.

Merrill, H. P., Portland.
Price, W. N., Richmond.
Washburn, G. E., Augusta.
Walton, R. D., Frankfort.

MARYLAND.

Davidson, C. F., Easton.
Goodman, J. M., Frederick.
Hall, R. M., Baltimore.
Harrison, H. T., Loch Raven.
Kahn, H., Baltimore.
Legge, J. E., Oakland.
McNeer, R. L., Baltimore.
Magruder, W. E., Cany Spring.
Spear, I. J., Baltimore.
Seymour, W. S., Trappe.
Wilcox, F. W., Baltimore.

MASSACHUSETTS.

Bacon, T. S., Cambridge.
Chase, E. L., Shrewsbury.
Cunningham, J. H., Jr., Boston.
Dwight. Thos., Nahant, Mass.
Glendenning, R. T., Manchester.
Hunt, W. O., Newtonville.
Haines, I., Cambridge.
Hubbard, J. C., Boston.
Jackson, H. B., Melrose.
Murdock, F. W., Brockton.
McPherson, G. E., S. Boston.
Morse, F. L., Somerville.
Murphy, E. M., Lowell.
Newhall, H. W., Lynn.
Nichols, J. H., Tewksbury.
Osborne, C. A., Worcester.
Porter, R. B., North Easton.
Richardson, F. L., Concord.
Tyrode, M. V., Boston.
Trainor, J. B., Fall River.
Wadsworth, O. F., Boston.
Whiton, R. K., Quincy.

MICHIGAN.

Baird, R. H., Howell.
Brook, J. D., Grandville.
Bryant, S. E., Dowagiac.
Elmer, W. P., Ann Arbor.
Hart, A. O., Maple Rapids.
Hewitt, H. W., Detroit.
Johnson, B. F. P., Rosebush.
McCarroll, Wm., Pontiac.
McKnight, E. E., Alpena.
Matchette, W. H., Hancock.
McBean, Jas. C., Applegate.
Shattuck, G. S., Detroit.
Sigel, T., Detroit.
Wessinger, J. A., Ann Arbor.

MINNESOTA.

Barsness, N. O. N., St. Paul.
Cowles, D. C., Minneapolis.
Dart, L. O., Minneapolis.
Hougan, O. M., Fergus Falls.
Pare, L. T., Duluth.
Rutledge, J. W., Minneapolis.
Salter, W. H., Duluth.
Stuart, J. H., Minneapolis.
Sawyer, H. P., Goodhue.
Theissen, W. N., Henderson.
Whitacre, J. C., St. Paul.

MISSISSIPPI.

Rauch, E. S., Vicksburg.
Simmons, C. L., McBride.

MISSOURI.

Austin, M. B., Brunswick.
Clagett, O. F., Jamesport.
Crawford, H. S., Harrisonville.
Davenport, R. G., Trenton.
Fleming, A. W., St. Louis.
Guibor, H. F., St. Louis.
Gashwiler, —, Novinger.
Hall, D. W., Kansas City.
Matlock, C. E., St. Louis.
Moore, E., St. Louis.
Miller, H., Kansas City.
Schulte, F. A., St. Louis.
Smith, B. T., Newburg.
Trimble, W. K., Kansas City.

MONTANA.

Lilly, A. H., Butte.
Moore, T. B., Butte.
Pampol, B. L., Livingston.
Pigot, C. T., Butte.

NEBRASKA.

Guttery, J. D., Valparaiso.
Isaacs, D., Winside.
Kraft, F. E., So. Auburn.
Quigley, D. T., No. Platte.
Robbins, E. E., Hastings.
Smrha, V. V., Milligan.

NEW HAMPSHIRE.

Locke, E. M., Nashau.
Palmer, H., Plymouth.

NEW JERSEY.

Baker, R. D., Summit.
Drummond, E. A., Newark.
Hoagland, G. G., Keyport.
Leonard, E., Jersey City.
Martland, W. H., Newark.

NEW MEXICO.

Smith, H. M., Las Vegas.
Thomson, R. J., Santa Rosa.
Yoakam, F. A., Cerrillos.

NEW YORK.

Benedict, A. J., Newburgh.
Berlin, F. F. R., New York.
Cooke, W. S., New York.
Conklin, R. C., Batavia.
Comfort, C. G. V., Rochester.
Dort, E., Buffalo.
Duggan, John, Albion.
Eytinge, O. J., Brooklyn.
Fuller, N. H., Friendship.
Friedman, L. A., New York.
Gross, M., New York.
Grady, J. J., New York.
Glenny, W. H., Buffalo.
Griggs, E. C., Ithaca.
Herst, S., New York.
Hopkins, F. T., New York.
Holland, A. L., New York.
Jackson, C. R. ,New York.
Latham, O. N., Bolivar.
Leibermann, J. M., New York.
Lewson, M., New York.
Lo Pinto, J., New York.
Lytle, C. G., Geneva.
McBurney, Charles, New York.
Meisburger, W., Buffalo.
Mooney, L. M., New York.
MacCoy, C., Brooklyn.
McParlan, J. P., New York.
Neal, V. F., Ellenville.
Nicolai, C., New York.

State Boards of Registration

COMING EXAMINATIONS.

State Board of M [illegible] California, San Francisco, August 15. Secreta [illegible] San Francisco.

Wyoming State [illegible] aminers, State Capitol, Cheyenne, Wyo., Sep [illegible] S. B. Miller, Laramie.

Massachusetts Bo [illegible] Medicine, State House, Boston, September 1 [illegible] Harvey, Boston.

Arkansas July Report.—Dr. J. P. Runyan, secretary of the State Medical Examining Board of the Arkansas Medical Society, reports the examination held at Little Rock, July 11, 1905. The number of subjects examined in was 7; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 28, of whom 19 were undergraduates; 18 passed, and 10 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
College of P. and S., Chicago (undergraduate)		85
Fisk University	(1900)	85
Flint Med. Coll. (undergraduates) 82, 76;	(1905)	80
Memphis Hosp. Med. Co [illegible]		76
Barnes Med. Coll. ...([illegible]		81
Washington University [illegible]	(1903)	84
Tulane and Vand [illegible]		92
Tulane Universit [illegible] ;	(1905)	94
Shaw University		81
Milwaukee Med. Coll.		94
University of Nashville (undergraduate)		83
University of Missouri (undergraduate)		75
Medico-Chirurgical, Kansas City	(1905)	78

FAILED.

College.	Year Grad.	Per Cent.
Galveston and Memphis Hosp. Med. Coll. (undergraduate)		43
University of Missouri (undergraduate)		53
University of Nashville and Baylor Med. Coll. (undergraduate)		69
Universities of Arkansas and Nashville (undergraduate)		58
Flint Med. Coll.	(1905)	59
Tulane University (undergraduate)		66
Louisville Med. Coll. and Tulane Univ. (undergraduate)		63
Knoxville Med. Coll.	(1903)	69
Memphis Hosp. Med. Coll. (undergraduate)		58
Memphis Hosp. Med. Coll. and Barnes Med. Coll. (undergraduate)		67

South Carolina June Report.—Dr. W. M. Lester, secretary of the South Carolina State Board of Medical Examiners, reports the written examination held at Columbia, June 13-15, 1905. The number of subjects examined in was 18; total number of questions asked, 95; percentage required to pass, 75, and not less than 60 on any subject. The total number of applicants examined was 66, of whom 44 passed and 22 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Medical Coll. of the State of South Carolina,	(1900) 89.6; (1905)	77.2, 80.1, 81.2, 81.8, 82.1 82.6, 82.8, 83.2, 83.6, 83.8, 85, 85.3, 85.3, 86.3, 87.1, 88.1, 88.5, 93.2.
University of Pennsylvania	(1901) 89.1; (1903)	89.6
Howard University	(1904)	81.7
University of Kentucky	(1904)	79.2
North Carolina Med. Coll.	(1902) 76; (1905)	80.1
College of P. & S., Chicago	(1905)	86.1
University of Nashville	(1905)	75.5, 82.3, 87, 92.7
Leonard Med. Coll.	(1902)	75
University of Maryland	(1904)	80.5, 81, 82, 78.6, 75, 83.7
Jefferson Med. Coll.	(1905)	78, 83.3
Tulane University	(1905)	79.7, 81
College of P. & S., Atlanta	(1900)	81.1
Baltimore Med. Coll.	(1905)	84
College of P. and S. Baltimore	(1904)	75

FAILED.

College.	Year Grad.	Per Cent.
Medical Coll. of the State of South Carolina,	(1901) 60.2; (1905)	79.3,* 70.2, 78.6,* 76.8.* 78.8,* 79.8.*
North Carolina Med. Coll.	(1903)	80.6*
University of the South	(1904)	74.1**
University of Kentucky	(1904)	79*
Leonard Med. Coll.	(1889) 66.5; (1905)	75*
Chattanooga Med. Coll.	(1905)	55.3, 59.3
University of Tennessee	(1905)	52.2
Meharry Med. Coll.	(1905)	75*
Maryland Med. Coll.	(1904) 56.6; (1905)	39.3
University of Maryland	(1905)	79.3*

Turner, W. K., Seattle, Wash.
Turner, S. T., El Paso, Texas.
Tuthill, J. A., Le Roy, Ill.
Vaughn, J. B., Castlewood, S. D.
Watkins, T. R., Aberdeen, Wash.
Watson, W. C., Lima, Ohio.
Watson, Wm. Newbold, Philadelphia, Pa.
Welch, John Frederick, Quincy, Mass.
Wheeler, C. H., Portland, Ore.
Wiltsie, S. F., Seattle, Wash.

Wood, C. B., Honolulu, Hawaii.
Wood, J. F., Condon, Ore.
Yerdon, Charles F., Brooklyn, N. Y.
Young, James A., Pearl, Idaho.

NEW MEMBERS.

List of new members of the American Medical Association during the month of July, 1905:

ALABAMA.

Dugan, R. H., Prairie Villa.
Fields, E. T., Ensley.

ARIZONA.

Cassady, D., Bisbee.
Hughes, H. A., Phoenix.
Olcott, A. W., Tucson.

ARKANSAS.

Eastman, E. H., Hot Springs.
Hederick, A. R., Booneville.
Parker, J. L., Snyder.
Sweatland, A. E., Little Rock.
Steed, C. J., Hurricane.

CALIFORNIA.

Avey, J. L., Redlands.
Bryant, E. A., Los Angeles.
Barber, D. C., Los Angeles.
Black, J. A., San Francisco.
Brown, Geo. J., Smith River.
Breneman, J. T., Martinez.
Carlton, H. P., San Francisco.
Clark, Wm. A., San Leandro.
Cunnani, T. E., Ventura.
Crediford, D. B., Rialto.
Campbell, C. G., San Bernardino.
Cox, H. M., San Luis Obispo.
Dial, E. A., Santa Barbara.
Davis, S. F., Pomona.
Hesser, G. T., Folsom City.
Herbert. H., Los Angeles.
Hinkle. B. M., San Francisco.
King, E. D., Ukiah.
Kane, J. M., Oakland.
Kelly, A. S. Oakland.
Majors, E. A., Stoledad.
Milton, J. L., Oakland.
Magee, C. L., Los Angeles.
Meng, J. D., Chico.
Mules, J. H., East Auburn.
Nelson, L., San Francisco.
Nixon, A. W., Los Angeles.
Pond, G. P., San Francisco.
Reed, C. E., Redding.
Ryfkogel, H. A. L., San Francisco.
Richardson, N. E., Salinas.
Schmall, E., San Francisco.
Smyth, M. H., Stockton.
Southworth, M. A., San Jose.
Schlageter, H. J., San Francisco.
Troppmann, C. M., San Francisco.
Walker, J. R., Fresno.

COLORADO.

Bren. M. R., Denver.
Daniels, H. P., Colorado City
Epler. Crum, Pueblo.
Hutchinson, W., Del Agua.
Keeney, M. J., Pueblo.
Phelan, N. J., Denver.
Stubbs, A. L., La Junta.
Shere, O. M., Denver.
Wood, W. H., Greeley.
Wilkinson, W. W., Silverton.

CONNECTICUT.

Heady, E. B., Milford.
Lewis. J. B., Hartford.
Loomis, F. N., Derby.
McCabe, E. M., New Haven.
Smirnow, Louis, Bridgeport.
Streit, George, Middletown.
Witter, Wm., Norwich.
Young, C. B., Middletown.

DISTRICT OF COLUMBIA.

Biscoe, F. L., Washington.
Duffey, H. C., Washington.
Key, Sothoron, Washington.

GEORGIA.

Champion, W. L., Atlanta.

HAWAII.

Day, F. R., Honolulu.
Armitage, Edw., Wailuku, Mani.

IDAHO.

Boyd, T. O., Twin Falls.
Collister, Geo., Boise.
Coultchard, G. H., Idaho Falls.
Clouchek, H. W., Twin Falls.
Gritman, C. L., Moscow.
Hamilton, J. J., Caldwell.
Hall, O. L., Star.
Jordan, M. S., Grand Mound.
Moody, C. S., Sand Point.
Murray, J. H. Nampa.
Phillips, C. C., Lewiston.
Springer, W. D., Boise.

ILLINOIS.

Bailey, C. W., Hebron.
Bailey, G. T., Chicago.
Baldwin, B. H., Chicago.
Burch, G. W., Quincy.
Bussey, G. N., Chicago.
Bell, A., Chicago.
Clune, P. J., Ottawa.
Coone, B., Chicago.
Crowder, T. R., Chicago.
Crouch E. L., Jacksonville.
Conner, E. M., Chicago.
Dagg, T. L., Chicago.
Dicus, G. A., Streator.
Duncan, C. E., Flora.
Foster, T. J., De Soto.
Fiske, D., Chicago.
Gaebler, Arthur, Chicago.
Githens, W. K., Hamilton.
Greig, T. O., Chicago.
Hester, E. E., Paxton.
Hansen, G. H., Chicago.
Harper, J. E., Chicago.
Huey, W. B., Chicago.
Hamilton, J. W., Mt. Vernon.
Hassin, G. B., Chicago.
Frank, I., Chicago.
Kieene, F. R. C., Chicago.
Lemen, H. R., Alton.
Leonard. E. F., Chicago.
Lurie, W. A., Chicago.
Lyon, C. E., Toledo.
MacDowell, E. G., Chicago.
McCornack, E. A., Elgin.
Merki, E. J., Chicago.
Miller, G. P., Chicago.
Miller, J. E., Pittsfield.
McGuire, J. W., Chicago.
Peter, R., Chicago.
Presler. H. M., Cullom.
Presnell, J. F., Chicago.
Phillips, D. C., Chicago.
Podstata, V. H., Dunning.
Rosenow, E. C., Chicago.
Reid, D. W., Jacksonville.
Rochow, C. J. F., Rock Island.
Remmen, N. E., Chicago.
Rudy, F. T., Champaign.
Vary, W. H., Chicago.
Vaupell, W. R., Chicago.
Washburn, W. E., Kewanee.
Whise, M., Chicago.

INDIANA.

Brill, J. H., Indianapolis.
Black, F. W., Ligonier.
Calvin, J. Carruthers, Ft. Wayne.
Cooper, J. A., Terre Haute.
Daugherty, C. A., South Bend.
Freeland, J. L., Indianapolis.
Hawn, C. E., Little York.
Mattison, J. A., Nat. Mil. Home.
McFarlin, J. T., Williams.
Miller, H. H., Galveston.
Niblack, E. S., Terre Haute.
Ritter, M. T., Angola.
Whitesides, L. L., Franklin.
Westover, R. L., Indianapolis.

IND. TERRITORY.

Looney, R. E., Lindsay.

IOWA.

Burgess, J. A. W., Iowa Falls.
Brubaker, J. F., Hubbard.
Bridgman, J. C., Radcliffe.
Breniman, E. M., Ackley.
Butler, F. P., Whitten.
Bartran, R. T., Albia.
Corbit, A. B., Wyoming.
Caldwell, J. W., Steamboat Rock.
Caldwell, J. Willard, Steamboat Rock.
Conner, F. H., Nevada.
Cronk, C. H., Bloomfield.
Dittmer, H. A., Manchester.
Evans, F. J., Iowa Falls.
Hobson, A. J., Hampton.
Hunter, W. W., Monticello.
Hartman, F. T., Waterloo.
Jones, E. H., Eldora.
Koeneman, E. O., Eldora.
Lowder, Wm., New Providence.
McLaughlin, C. W., Washington.
Miller, J. J., Ackley.
Moore, M. F., Martinsburg.
Mabee, C. O., New Providence.
Marsh, W. E., Eldora.
Morton, L. B., Iowa Falls.
Murphy, F. J., Sioux City.
Pagelson, O. H., Iowa Falls.
Petrovitsky, J. S., Cedar Rapids.
Rabe, F. L., Hubbard.
Roberts, W. P., Cleghorn.
Scarborough, H. V., Grand Junction.
Sanders, W. E., Alta.
Stone, Guy, Keswick.
Sherman, A. M., Grinnell.
Trimble, C. S., Buckeye.
Underwood, R. B., Eldora.
Vroom, C. W., Ackley.
Wood, P. R., Marshalltown.
Walker, J. R., Ft. Madison.
Whitney, W. E., Eldora.
Willett, C. C., Whitten.
Wray, C. M., Lawton.
White, E. E., Huxley.

KANSAS.

Boss, J. H., Weir City.
Buley, D. G., Valley Center.
Blades, S. T., Scottsville.
Chadwick, I. B., Tyro.
Fabrigur, A. H., Wichita.
Holt, T. T., Geudo Springs.
Hartwell, G. N., Jamestown.
Hardesty, H. O., Jennings.
Humfreville, D. W., Waterville.
McManis, J. E., Havensville.
Nichols, S., Herington.
Nye, W. W., Hiawatha.
Shelton, F. W., Independence.
Snyder, H. G., Seneca.
Spitler, S. W., Wellington.
Shannon, L. W., Hiawatha.
Ullman, J. F., Simpson.
Wilson, W. P., Westmoreland.

KENTUCKY.

Hendon, G. A., Louisville.
Lex, E. A., Louisville.
Mosely, J. C., Henderson.
Price, A. D., Harrodsburg.

LOUISIANA.

Burley, C. H., Monterey.
Feucht, E. P., Laplace.

MAINE.

Merrill, H. P., Portland.
Price. W. N., Richmond.
Washburn, G. E., Augusta.
Walton, R. D., Frankfort.

MARYLAND.

Davidson, C. F., Easton.
Goodman, J. M., Frederick.
Hall, R. M., Baltimore.
Harrison, H. T., Loch Raven.
Kahn, H., Baltimore.
Legge, J. E., Oakland.
McNeer, R. L., Baltimore.
Magruder, W. E., Cany Spring.
Spear, I. J., Baltimore.
Seymour, W. S., Trappe.
Wilcox, F. W., Baltimore.

MASSACHUSETTS.

Bacon, T. S., Cambridge.
Chase, E. L., Shrewsbury.
Cunningham, J. H., Jr., Boston.
Dwight, Thos., Nahant, Mass.
Glendenning, R. T., Manchester.
Hunt, W. O., Newtonville.
Haines, I., Cambridge.
Hubbard, J. C., Boston.
Jackson, H. B., Melrose.
Murdock, F. W., Brockton.
McPherson, G. E., S. Boston.
Morse, F. L., Somerville.
Murphy, E. M., Lowell.
Newhall, H. W., Lynn.
Nichols, J. H., Tewksbury.
Osborne, C. A., Worcester.
Porter, R. B., North Easton.
Richardson, F. L., Concord.
Tyrode, M. V., Boston.
Trainor, J. B., Fall River.
Wadsworth, O. F., Boston.
Whiton, R. K., Quincy.

MICHIGAN.

Baird, R. H., Howell.
Brook, J. D., Grandville.
Bryant, S. E., Dowagiac.
Elmer, W. P., Ann Arbor.
Hart, A. O., Maple Rapids.
Hewitt, H. W., Detroit.
Johnson, B. F. P., Rosebush.
McCarroll, Wm., Pontiac.
McKnight, E. E., Alpena.
Matchette, W. H., Hancock.
McBean, Jas. C., Applegate.
Shattuck, G. S., Detroit.
Sigel, T., Detroit.
Wessinger, J. A., Ann Arbor.

MINNESOTA.

Barsness, N. O. N., St. Paul.
Cowles, D. C., Minneapolis.
Dart, L. O., Minneapolis.
Hougan, O. M., Fergus Falls.
Pare, L. T., Duluth.
Rutledge, J. W., Minneapolis.
Salter, W. H., Duluth.
Stuart, J. H., Minneapolis.
Sawyer, H. P., Goodhue.
Theissen, W. N., Henderson.
Whitacre, J. C., St. Paul.

MISSISSIPPI.

Rauch, E. S., Vicksburg.
Simmons, C. L., McBride.

MISSOURI.

Austin, M. B., Brunswick.
Clagett, O. F., Jamesport.
Crawford, H. S., Harrisonville.
Davenport, R. G., Trenton.
Fleming, A. W., St. Louis.
Gulbor, H. F., St. Louis.
Gashwiler, —, Novinger.
Hall, D. W., Kansas City.
Matlock, C. E., St. Louis.
Moore, E., St. Louis.
Miller, H., Kansas City.
Schulte, F. A., St. Louis.
Smith, B. T., Newburg.
Trimble, W. K., Kansas City.

MONTANA.

Lilly, A. H., Butte.
Moore, T. B., Butte.

State Boards of Registration

COMING EXAMINATIONS.

State Board of Medical Examine[illegible] [illegible]ancisco, August 15. Secretary, Charles L. [illegible]

Wyoming State Board of Medi[illegible] [illegible]Capitol, Cheyenne, Wyo., September 6. Sec[illegible] [illegible]imie.

Massachusetts Board of Registra[illegible] [illegible] House, Boston, September 12-13. Secretar[illegible]

Arkansas July Report.—Dr. J. P. Runyan, secretary of the State Medical Examining Board of the Arkansas Medical Society, reports the examination held at Little Rock, July 11, 1905. The number of subjects examined in was 7; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 28, of whom 19 were undergraduates; 18 passed, and 10 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
College of P. and S., Chicago (undergraduate)		85
Fisk University	(1900)	85
Flint Med. Coll. (undergraduates) 82, 76;	(1905)	80
Memphis Hosp. Mec [illegible]		76
Barnes Med. Coll.		81
Washington Univers[illegible]	(1903)	84
Tulane and Vander[illegible]		92
Tulane University	(1905)	94
Shaw University (undergraduate)		81
Milwaukee Med. Coll.		94
University of Nashville (undergraduate)		83
University of Missouri (undergraduate)		75
Medico-Chirurgical, Kansas City	(1905)	78

FAILED.

College.	Year Grad.	Per Cent.
Galveston and Memphis Hosp. Med. Coll. (undergraduate)		43
University of Missouri (undergraduate)		53
University of Nashville and Baylor Med. Coll. (undergraduate)		69
Universities of Arkansas and Nashville (undergraduate)		58
Flint Med. Coll.	(1905)	59
Tulane University (undergraduate)		66
Louisville Med. Coll. and Tulane Univ. (undergraduate)		63
Knoxville Med. Coll.	(1903)	69
Memphis Hosp. Med. Coll. (undergraduate)		58
Memphis Hosp. Med. Coll. and Barnes Med. Coll. (undergraduate)		67

South Carolina June Report.—Dr. W. M. Lester, secretary of the South Carolina State Board of Medical Examiners, reports the written examination held at Columbia, June 13-15, 1905. The number of subjects examined in was 18; total number of questions asked, 95; percentage required to pass, 75, and not less than 60 on any subject. The total number of applicants examined was 66, of whom 44 passed and 22 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Medical Coll. of the State of South Carolina, (1900) 89.6; (1905) 77.2, 80.1, 81.2, 81.8, 82.1 82.6, 82.8, 83.2, 83.6, 83.8, 85, 85.3, 85.3, 86.3, 87.1, 88.1, 88.5, 93.2.		
[illegible] (1901) 89.1;	(1903)	89.6
[illegible]	(1904)	81.7
[illegible]	(1904)	79.2

Chattanooga Med. Coll.	(1905) 55.3,	59.3
University of Tennessee	(1905)	52.2
Meharry Med. Coll.	(1905)	75*
Maryland Med. Coll. (1904) 56.6;	(1905)	39.3
University of Maryland	(1905)	79.3*

Tulane University	(1904)	77.2*
Knoxville Med. Coll.	(1904)	69.7

* Below 60 per cent. on one or more subjects.

** Left examination on account of illness.

The general average attained by all representatives of the medical college of the state of South Carolina, who passed, was 84.5.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, week ending Aug. 5, 1905:

Halloran, Paul S., asst.-surgeon, leave of absence extended two months.

Ragan, Chas. A., asst.-surgeon, granted thirty days' leave of absence.

Clayton, Jere B., asst.-surgeon, assigned to duty at Fort Leavenworth, Kan., and granted fifteen days' leave of absence before reporting for duty.

Baker, David, asst.-surgeon, relieved from duty at Fort Leavenworth, Kans., and ordered to Fort Robinson, Neb., for duty.

Porter, Ralph S., asst.-surgeon, relieved from duty at Fort Niobrara, Neb., and ordered to Manila, P. I., for duty.

Woodbury, F. T., asst.-surgeon, ordered to accompany 3d Battalion, 5th Infantry, from Plattsburg Barracks, N. Y., to Sea Girt, N. J., for duty, and return with same.

Woodall, Wm. P., asst.-surgeon, left from detached duty at Fort Oglethorpe, Ga., on fifteen days' leave of absence.

Roberts, William, asst.-surgeon, ordered to accompany detachment from Fort Hamilton, N. Y., to Sea Girt, N. J., on Sept. 12, 1905, and remain at camp in charge of the medical department.

Wing, Franklin F., dental surgeon, granted leave of absence for one month, fifteen days, from Fort Riley, Kan.

Marshall, John S., examining and supervising dental surgeon, returned to the Presidio of San Francisco, from attendance on the American Medical Association and the Lewis and Clark Dental Congress at Portland, Ore.

[illegible] dental surgeon, returned to Vancouver Bar[illegible]om attendance on the Lewis and Clark Dental [illegible] Ore.

[illegible] contract surgeon, returned to Fort Douglas, Utah, from duty in the field, Strawberry Valley, Utah.

Macy, Fred S., contract surgeon, left Allegheny Arsenal, Pa., on leave of absence for ten days.

Warwick, Clarence A., contract surgeon, arrived from the Philippines Division on the transport *Warren*, for four months' leave of absence.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending Aug. 5, 1905:

Shipp, E. M., surgeon, orders to the *Charleston* revoked; ordered to the Navy Yard, New York, N. Y.

J. F. Leys and J. C. Thompson, surgeons, commissioned surgeons, with rank of lieutenant-commander, from March 3, 1903.

Furlong, F. M., P. A. surgeon, ordered to the Bureau of Medicine and Surgery, Navy Department.

Dessez, P. T., asst.-surgeon, ordered to the *Charleston*.

Ledbetter, R. E., P. A. surgeon, detached from the *Detroit* and ordered to the Naval Hospital, Boston.

Wise, J. C., medical director, detached from duty as a member of the Naval Medical Examining Board and Naval Retiring Board, Washington, D. C., August 10, and ordered to duty as president of the Naval Medical Examining Board, Naval Medical School, and to command Naval Medical School.

Marmion, R. A., medical director, detached from duty as president of the Naval Medical Examining Board, Naval Medical School, Washington, D. C., and from command of the Naval Medical School and ordered to duty as a member of the Naval Medical Examining Board and Naval Retiring Board, Mills Building, Washington, D. C.,

Munger, C. B., asst.-surgeon, ordered to the Naval Hospital, Norfolk, Va.

Marshall, E. R., asst.-surgeon, ordered to the Naval Hospital, Washington, D. C.

May, H. A., Asst.-surgeon, detached from the *Franklin* and ordered to the *Iowa*.

Sellers, F. E., acting asst.-surgeon, ordered to the *Franklin*.

Webb, U. R., P. A. surgeon, detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the Naval Academy.

Jennes, B. F., asst.-surgeon, detached from the *Iowa* and ordered home to wait orders.

Cole, H. W., asst.-surgeon, orders of July 31 modified; ordered to the Maine.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and noncommissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Aug. 2, 1905:

Magruder, G. M., surgeon, designated as member of Revenue Cutter Service retiring board at San Francisco, Aug. 10, 1905.

Wertenbaker, C. P., surgeon, relieved from duty at Havana, Cuba, and directed to proceed to Tampa, Fla., Montgomery, Ala., and Atlanta, Ga., for special temporary duty.

Cumming, H. S., P. A. surgeon, designated as member of Revenue Cutter Service retiring board at San Francisco, August 10.

Corput, G. M., P. A. surgeon, relieved from duty at the Marine Hospital, New Orleans.

Currie, D. H., P. A. surgeon, department letter of July 1, 1905, granting leave of absence for two months from July 6, 1905, amended to read two months from July 18.

Goldberger, Jos., P. A. surgeon, to proceed to Vicksburg, Miss., and Shreveport, La., and other places in Mississippi and Louisiana, for special temporary duty.

Berry, T. D., P. A. surgeon, to rejoin station at New York, and then to proceed to New Orleans and to report to Surgeon J. H. White for special temporary duty.

Burkhalter, J. T., asst.-surgeon, leave of absence for one month on account of sickness, granted by bureau letter of July 17, 1905, revoked.

Wightman, W. M., asst.-surgeon, granted extension of leave of absence for seven days from August 9.

Spratt, R. D., asst.-surgeon, to proceed to Gulf quarantine station and report to medical officer in command for temporary duty.

Hallett, E. B., acting asst.-surgeon, granted leave of absence for four days from July 28.

Kennard, K. S., acting asst.-surgeon, granted leave of absence for twenty-one days from August 7.

Marr, H., acting asst.-surgeon, granted leave of absence for twenty-one days, from August 21.

Sinclair, A. N., acting asst.-surgeon, department letter of July 10, 1905, granting leave of absence for thirty days from July 8, amended to read thirty days from July 12.

Williamson, S. D., acting asst.-surgeon, granted extension of leave of absence for twenty-two days, from July 31.

MacDowell, W. F., pharmacist, granted leave of absence for thirty days, from August 10.

Carlton, C. G., pharmacist, leave of absence for twenty-nine days, from July 24, 1905, revoked.

Morris, G. A., pharmacist, to proceed to New Orleans, and report to Surgeon J. H. White for special temporary duty.

BOARD CONVENED.

Board to meet at the Marine Hospital, Portland, Me., July 31, 1905, for the physical examinaton of an officer of the Revenue Cutter Service. Detail for the board: Surgeon W. P. McIntosh, chairman; Acting Assistant Surgeon A. F. Stuart, recorder.

PROMOTIONS.

Assistant Surgeon M. W. [illegible] [illegible]ecess) as P. A. surgeon, to rank as such [illegible]

Assistant Surgeon B. H. Ear[illegible] as P. A. surgeon, to rank as such from [illegible]

Assistant Surgeon C. C. Pierce, commissioned (recess) as P. A. surgeon, to rank as such from June 27, 1905.

Health Reports.

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the period from July 15 to July 29, 1905:

SMALLPOX—UNITED STATES.

California: Los Angeles, July 8-15, 4 cases.
District of Columbia: Washington, July 15-22, 1 case.
Illinois: Chicago, July 15-22, 11 cases, 1 death.
Indiana: South Bend, July 15-22, 1 case.
Michigan: Grand Rapids, July 15-22, 5 cases, 1 death.
Missouri: St. Joseph, July 8-15, 4 cases.
New York: Rome, July 15-22, 1 case.
Ohio: Cincinnati, May 19-June 2, 9 cases; June 8-23, 6 cases.
Pennsylvania: York, July 15-22, 11 cases.
Wisconsin: Appleton, July 15-22, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Colony, Cape Town, June 18-24, 3 cases.

Brazil: Rio de Janeiro, June 11-July 2, 32 cases, 21 deaths.

Chile: At Ports, June 14, present.

France: Lyon, July 2-9, 1 case; Paris, July 1-8, 10 cases, 1 death.

Great Britain: Birmingham, July 1-8, 1 case; Bristol, July 8-15, 1 case; Cardiff, 3 cases; [illegible] [illegible]-8, 5 cases.

Greece: Athens, June [illegible]

India: Bombay, June [illegible] June 10-17, 2 deaths; Karachi, June 11 [illegible] [illegible]as, June 10-23, 5 deaths.

Italy: General, June 29-July 6, 8 cases; Catania, 3 deaths; Messina, June 25-July 2, 1 case; Palermo, July 1-8, 1 case.

Mexico: City of Mexico, June 24-July 15, 20 cases, 10 deaths.

Canada: New Brunswick, St. John, July 14, 1 case, imported.

Panama: Bocas del Toro, July 1-7, 1 case, imported.

Russia: Moscow, June 17-July 1, 9 cases, 6 deaths; Odessa, June 25-July 8, 10 cases, 1 death; St. Petersburg, June 24-July 1, 13 cases, 2 deaths.

Spain: Barcelona, June 1-10, 2 cases.

Turkey: Constantinople, June 18-25, 4 cases.

Venezuela: Maracaibo, June 6-July 2, 4 cases, 4 deaths.

West Indies: Grenada, June 15-29, 5 cases.

YELLOW FEVER—UNITED STATES

Florida: Tampa, July 28, 1 case.
Louisiana: New Orleans, July 21-26, 73 cases, 22 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, June 11-July 2, 84 cases, 40 deaths.

[illegible] [illegible]elize, July 6-13, 1 case.

[illegible] July 7, present; Puerto Cortez, July 1-17, 20 [illegible] Pedro, July 15, 200 cases; 15 deaths.

Mexico: Coatzacoalcos, July 9-15, 2 cases; Tierra Blanca, 3 cases, 1 death; Vera Cruz, 1 case, July 23-25, 4 cases.

Panama: Colon, July 2-11, 5 cases, 1 death.

CHOLERA.

India: Bombay, June 13-20, 3 cases; Calcutta, June 10-17, 8 deaths; Madras, June 17-23, 1 death.

PLAGUE—FOREIGN.

Africa: Cape Colony, East, London, June 3-24, 6 cases, 3 deaths; King Williams Town, June 17-24, 1 case.

Brazil: Rio de Janeiro, June 18-July 2, 6 cases, 2 deaths.

China: Hongkong, May 13-20, 20 cases, 19 deaths.

Egypt: General, June 10-24, 25 cases, 16 deaths.

India: Bombay, June 4-27, 221 deaths; Calcutta, June 10-17, 37 deaths; Karachi, June 11-25, 85 deaths; Madras, June 10-16, 1 death.

Japan: Formosa, May 1-31, 734 cases, 622 deaths, June 1-20, 213 cases, 184 deaths.

Peru: Callao, June 1-10, 1 case; Cerro de Paseo, 1 case, 1 death; Lima, June 1-10, 6 cases, 2 deaths; Mollendo, June 1-10, 1 case, 2 deaths.

Society Proceedings

AMERICAN ASSOCIATION OF LIFE INSURANCE EXAMINING SURGEONS.

Sixth Annual Meeting, held at Portland, Ore., July 10, 1905,

The President, Dr. Denslow Lewis, Chicago, in the Chair.

(Concluded from Page 418.)

The Recognition of Drug Addictions in Life Insurance.

Dr. T. D. Crothers, Hartford, Conn., said that 30 per cent. or more of all alcoholics also take drugs. He divided the drug-takers into two classes, the simple and the complex, and gave a summary of some of the facts on which the recognition of drug addiction must turn. He believes that a careful examination of the sight, hearing, taste and smell will generally show the condition, notwithstanding the denials of the applicant, and that when psychologic studies of applicants for life insurance are made with as much minuteness as examinations of the heart, urine and blood, the hazardous risk of drug-takers as healthy normal persons will be eliminated.

Dr. J. T. Priestley, Des Moines, thought that the insurance companies suffered more from the drug-taker than any other class of people.

Dr. J. Allen Gilbert, Portland, thought too little attention was given to this phase of examinations and referred to a series of tests which he employed in examining the nervous system.

The address of the president, Dr. Denslow Lewis, Chicago, was on the subject: "The Medical Examiner and His Work."

Women as Risks.

Dr. Mae H. Cardwell, Portland, Ore., commented on the physical and moral conditions of women which make for or against their eligibility as risks in insurance. Until women have become financial independents they will never be equal factors for the consideration of the companies. Statistics of the life of the female should be created. The mortality in men from the effects of liquor is vastly in excess of that of women. Deaths from kidney infection through gonorrhea are as common among men as are deaths in women from the same infection of the generative apparatus. She strongly recommended that physical examination of women for insurance be extended to palpation and inspection of the pelvis, unless satisfactory evidence is given that the organs are healthy. Loyalty to the companies should prompt a warning to the applicants against habits which may develop disease, yet this warning may be exaggerated by a nervous woman. Suicide in business women is a danger to be considered.

DISCUSSION.

Dr. H. G. Brainerd, Los Angeles, thought the position of women as risks a question yet to be determined. It would add much to the willingness of companies to take such risks if it were known that the pelvic organs were in good condition.

Dr. J. Allen Gilbert, Portland, insisted the pelvis ought to be examined.

Dr. Amos, Portland, spoke of the difficulty of finding the evidence of gonorrhea even when the disease is known to exist.

Dr. W. J. Means, Columbus, said that in his experience in the examination of women for fraternal insurance he has found a lower mortality among women than among men.

Dr. A. Merrill Miller, Danville, spoke of the difficulty of examining a woman at her home, and of the reluctance of a woman to submit to the ordeal of an examination when she realizes its extent.

Dr. J. R. Wetherbee, Portland, referred to the necessity for pelvic examination brought to his attention by operations. The conditions which caused the operations would have been revealed by a pelvic examination at the time insurance was issued.

Dr. Cardwell said that she believed a large majority of women would submit to pelvic examinations if the requirements were printed in the application. She does not feel that the drug habit is so important a question among women as that of suicide.

The Relation of the Life Insurance Examiner to Local Sanitation.

Dr. J. R. Wetherbee, Portland, said that the function of a physician as a life insurance examiner should not only be to report the facts concerning a given risk, but to see that the forces in his locality which tend to raise or lower the mortality receive attention. Few physicians know where the sewers of their respective cities empty their contents. In his opinion equal responsibility rests on the physician in the matter of educating the public in the prevention of tuberculosis. He called attention to combination policies which furnish indemnity against loss of health as well as loss of life on the same principles as fire insurance. Should this policy become universal, the responsibility of the insurance examiner for the local sanitary conditions would be even greater. Wetherbee attributed the reduction of mortality from typhoid in Portland to the introduction of absolutely pure water from the perpetual snows of Mt. Hood. From this standpoint alone much money is saved to the local life insurance companies.

DISCUSSION.

Dr. Denslow Lewis thought the amount of attention given by the public sanitarians not commensurate with the importance of the subject. He agreed with Dr. Wetherbee in his remarks concerning typhoid.

Dr. John S. Lankford, San Antonio, directed attention to the importance of educating the school children in matters of health. In San Antonio school children have studied the various stages of development of the mosquito and many have been killed by the children. Hence, malaria has greatly decreased. He believes that if the children are educated in this respect when they become citizens the sanitary conditions will be properly adjusted.

Dr. M. H. Cardwell, Portland, thought the hope of the people was entirely with the young, and that this work should be taken up by educational boards. The subject of ventilation as a preventive of disease should be studied by insurance companies.

Suppurations in the Temporal Bone, and their Practical Relation to Life Insurance.

Dr. John F. Barnhill, Indianapolis, discussed the following phases: 1. What symptoms given by the patient and what pathologic conditions found in the diseased ear should be regarded as sufficiently dangerous to reject the applicant? 2. Under what circumstances as to the condition of the discharging ear may the applicant be considered a safe risk? 3. Under what conditions as to the diseased ear should the applicant's case be postponed, and when after medicinal or surgical treatment may insurance be safely issued? He believes that no just decision as to whether or not any applicant is non-insurable can be made unless there be taken into consideration the symptoms obtainable from the person himself, together with the absolute facts obtained from the most thorough, painstaking and accurate examination of the condition of the middle ear and its accessory cavities. There are many suppurating ears which may continue indefinitely, without serious risk to life. The deep cavities of the middle ear must be thoroughly inspected by an experienced aurist. In the present highly developed state of the otologic science there are but few discharging ears that can not be cured, and the patient, therefore, may become an entirely safe risk in so far as the ear condition is concerned.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held June 27, 1905.

The President, Dr. Dudley Tait, in the Chair.

Diaphragmatic Grooves on the Liver.

Dr. R. O. Moody stated that two classes of grooves occur on the liver, those running parallel to the ribs and apparently due to the impression left by the ribs on the liver, occurring most frequently in women who lace, and grooves running in the opposite direction, i. e., parallel to the falciform ligament, and which have been termed diaphragmatic grooves. These grooves are found in about 40 per cent. of bodies coming to autopsy, usually on the upper and anterior surface of the right lobe. They may be simple or multiple, as many as nine being found on one of the cases reported. In form they vary from mere slits to more or less wide furrows, being one to eighteen millimeters deep and one and a half to eleven centimeters long. They occur with greatest frequency in old people, but they may be found even in the fetus, three of the latter class being on record. Among the causes believed to be responsible for these grooves are congenital changes in the diaphragm, constriction of the thorax or abdomen by tight clothing, irregularities on the diaphragm produced by such causes as diaphragmatic pleurisy or local peritonitis and a relatively too rapid growth of the liver for the size of the abdominal cavity, which throws the former into folds.

Dr. George Blumer stated that he had often noticed these folds at autopsy and that they seemed to occur more frequently in women than in men, especially in women who had laced.

Dr. Dudley Tait called attention to the importance of a knowledge of these grooves, because they may be encountered at exploratory operations.

The Relation of Hodgkin's Disease to Lymphosarcoma.

Dr. H. W. Gibbons called attention to the great confusion that has arisen in the literature relative to the nature of certain enlargements of the lymphatic glands. Lymphosarcoma is distinguished from Hodgkin's disease, clinically, by the fact that the growth does not remain confined to the lymphatic tissue, but tends to infiltrate the surrounding tissues. Reed, Longcope, and Simmons have shown that Hodgkin's disease is characterized by a definite microscopic picture, differing from the microscopic pictures of both glandular tuberculosis and lymphosarcoma. Of the nine cases studied by the speaker, all presented the typical microscopic characteristics of Hodgkin's disease, with this important exception, that in every case the capsules of some glands were found to be infiltrated by the new growth. In 5 cases the new growth had broken through the capsule into the surrounding tissue and was enclosed by a new capsule. In two cases, involvement of the muscle, salivary glands, and fascia, had occurred. In the liver, in three cases, the tumor could be observed invading the walls of a vein and passing through them. Gibbons regards Hodgkin's disease as a malignant process rather than as a chronic infection. Yet it is still distinguishable from true lymphosarcoma by the nature of the cells that make up the tumor.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Spastic Constipation.

The differential diagnosis between atonic and spastic constipation is often very difficult and sometimes impossible, according to A. Albu of Berlin in *Med. Record.*

Spastic constipation, so he states, is found more frequently the more carefully it is sought for. In the female, at least 25 per cent. of the cases are of this form; and many of the most persistent cases of chronic constipation, refractory to all methods of treatment, are of this type. As the treatment of this form of constipation is diametrically opposite to the atonic form, it is not difficult to see why so many patients with constipation are treated for years without success.

Spastic constipation, according to Dr. Albu. is most frequently found in neurasthenic and hysterical individuals, most often females. They are weak, poorly nourished, somewhat pale and anemic and in the third or fourth decade of life.

A perfect knowledge of the syndrome of the malady, therefore, must be obtained in order to outline an intelligent course of treatment.

As these spasms sometimes develop on the basis of atony, every occasion for exciting them must be avoided. Every irritation of the intestines, and especially massage, which is very effective in the atonic form of constipation, must be avoided. He recommends the use of:

1. Warm or hot sitz baths for from 15 to 20 minutes at a time.

2. The application of hot compresses to the abdomen, which not only lessen the spasm, but relieve the colic.

3. Warm enemas of linseed oil or olive oil, one-quarter liter every evening, given in bed, with the hips elevated, or in the knee-elbow position, and retained over night if possible. The object of this treatment is not to produce bowel movements, but to act as a sedative on the spasm of the intestinal muscle, and should, therefore, remain in contact with it as long as possible.

4. As the best antispasmodic he recommends belladonna or atropin, the former given in the form of suppositories in doses of from three to five grains (.20-.30) two or three times daily.

5. Concerning the diet, the author has found a vegetable diet to be the best; the food must be carefully freed from all shells or other irritating particles. Patients may be allowed to partake of all sorts of wheaten bread, made of fine flour, prunes and cooked fruits, soups and broths. Milk is advisable if it does not constipate.

Alcohol, spices, cabbage, cucumbers, celery, radishes, cheese and similar articles of diet must be avoided.

6. The introduction of solid, hard rubber or wooden bougies into the rectum. These are allowed to remain in position for from 10 to 15 minutes every day. They should be lubricated with oil and introduced for five or ten centimeters.

The author does not recommend long and continual rest in bed, because the primary atony is, in this way, favored. On the other hand, he recommends exercise in the fresh air. A regular fattening cure is recommended only in the debilitated and intensely hysterical patients, and after other treatment has failed.

The large dose of belladonna recommended by the author should be noted.

Diarrhea and Dysentery.

Diarrhea, according to Hare in his *Pract. Ther.*, may be divided into: 1. That form due to catarrh, acute and chronic.

2. That form due to disordered innervation.

3. That due to diseased glands along the course of the gastrointestinal tract.

4. That due to ulceration, causing irritation and bloody stools.

The treatment of the first form, according to this author, consists primarily in the regulation of the diet, which should be chiefly of milk, boiled or predigested, or milk whey. Castor oil or other mild purges, such as magnesium sulphate, should be administered to clear the intestinal tract of fermenting food and mucus. To prevent griping he recommends that a sufficient amount of tincture of opium be added, also twenty to thirty (1.30-2.00) grams of sodium bicarbonate to render the bowel alkaline in reaction. A mustard plaster or other counter-irritant should be applied to the abdomen. If astringent treatment is necessary, he recommends the following combination:

℞.	Argenti nitratis	gr. ii	12
	Ext. hyoscyami	gr. v	30

M. Fiant pil. No. x. Sig.: One pill three times a day.

Or

℞.	Plumbi acetatis		
	Ext. opii, āā	gr. ii	12

M. Fiant pil. No. x. Sig.: One pill three times a day.

If the catarrhal state is persistent, no remedy compares to the ammonium chlorid in doses of grains five (.30) every four hours. It may be combined with licorice and water. If the catarrhal state is exceedingly chronic and obstinate, potassium iodid given in doses of from three to five grains (.20-.30) is of value.

If the discharges still remain profuse and the patient becomes weakened, the following is recommended by this author:

℞.	Acidi sulphurici arom.	ʒiss	6
	Spts. chloroformi	ʒii	8
	Tinct. opii camph.	℥ii	60
	Syr. zingiberis q. s. ad	℥iv	120

M. Sig.: One desertspoonful every four hours.

Or

℞.	Tinct. kino.			
	Tinct. catechu co., āā	℥i	30	
	Misturæ cretæ	℥iii	90	
	Aquæ cinnamomi q. s. ad	℥iv	120	

M. Sig.: Shake well and take one tablespoonful every three hours.

The second form of diarrhea, in which serous and watery purging is present, is that form in which the blood vessels of the intestine are relaxed and leaking, so to speak, and must be contracted, and for this purpose the following is recommended:

℞.	Acidi sulph. arom.	℥ss	15	
	Olei cajuputi	gtt. xl	2	65
	Ext. hematoxyli flu.	ʒii	8	
	Spts. chloroformi	ʒi	4	
	Syr. zingiberis q. s. ad	℥iii	90	

M. Sig.: One teaspoonful in water every two or three hours.

If the attacks are due to hepatic disorder, small doses of calomel should be administered to correct the inactivity of the liver and to clear out the intestinal tract.

The after-treatment consists in carefully regulating the diet, which should be composed of milk and milk foods.

The third class is found chiefly in children whose stools are fetid, green, spinach-like masses of half-digested food, and may be due to deficient glandular secretion. They are often cured by hydrochloric acid and pepsin. Powdered ipecac, grain ¼ to ½ (.015-.03) given three times a day is sometimes very valuable in this form of diarrhea.

The fourth type, dysentery, should be treated according to the cause. The intestinal tract should be cleared by calomel in full doses, unless contraindicated by great weakness of the patient. If the passages are slimy and bloody, 1/200 of a grain of the bichlorid of mercury every hour or two is of value. If much blood is presecent, high rectal injections of the following should be administered:

℞.	Aq. hamamelidis dest.			
	Aquæ, āā	℥ii	60	

M. Sig.: Use as a rectal injection.

Or the following may be used as a rectal enema:

℞.	Sodii boratis			
	Tinct. benzoini, āā	ʒi	4	
	Spts. camphoræ	℥i	30	
	Aquæ	Oii	1000	

M. Sig.: Use as a rectal injection.

If ulcers are present and old, the following is recommended:

℞.	Argenti nitratis	gr. x-xx		65-1.30
	Aquæ destil	Oi	500	

M. Sig.: Use as a rectal injection.

A salt solution may be used to follow the silver solution and to counteract its effect if it should prove too strong. Where mucus and pus are present Hare recommends irrigations of mercuric chlorid, 1/5000, or, if preferred for any reason, boric acid may be substituted in proportion of dram one (4.00) to the pint of water (500).

Tannic acid may also be used in the same manner as an astringent in strength of dram one (4.00) to a pint of water (500).

In the ordinary diarrheas occurring in summer, the following is recommended:

℞.	Acidi sulphurici arom	ʒii	8	
	Tinct. opii	ʒiss	6	
	Tinct. capsici	ʒss	2	
	Tinct. card. co.	ʒvi	24	
	Aq. menth. pip. q. s. ad	℥iv	120	

M. Sig.: One tablespoonful four times a day in water.

When diarrhea is present unaccompanied by pain, the following is serviceable:

℞.	Tinct. opii camphoratæ	℥i	30	
	Bismuthi subgal.	ʒiss	6	
	Syr. zingiberis q. s. ad	℥ii	60	

M. Sig.: Shake the bottle well and take one teaspoonful after each bowel movement.

In cases of diarrhea with vomiting, the following may be employed:

℞.	Bismuthi salicylatis			
	Sodii bicarb., āā	ʒiii	12	
	Liq. morph. hydrochlor. (1 per cent.)	ʒiss	6	
	Infusi calumbæ, q. s. ad	℥iv	120	

M. Sig.: Shake well and take one tablespoonful every four hours until the symptoms are relieved.

Beasley recommends the following combinations, containing hematoxylin, in the treatment of the different forms of diarrhea:

℞.	Cretæ prep.	gr. xv	1	
	Pulv. tragacanthæ	gr. ii		12
	Syr. simplicis			
	Tinct. Warburgii (N. F.), āā	ʒss	2	
	Decoct. hematoxyli (5 per cent.) q. s. ad.	℥i	30	

M. Sig.: At one dose and repeat three times daily.

[Warburg's tincture contains quinin gr. x (65) to the ounce (30), which is composed of aromatics.]

Or the following may be substituted for the foregoing combination:

℞.	Bismuthi salicylatis	gr. x		65
	Mucil. tragacanthæ	ʒii	8	
	Decoct. hematoxyli, q. s. ad	℥i	30	

M. Sig.: At one dose and the amount repeated once every four hours.

℞.	Ext. hematoxyli liq.	ʒss	2	
	Tinct. opii	m. v		30
	Aquæ caryophylli q. s. ad	℥i	30	

M. Sig.: One such dose every four hours in cases of chronic diarrhea.

Or

℞.	Creosoti	m. ii		12
	Ext. hematoxyli liq.	ʒi	4	
	Misturæ cretæ q. s. ad	℥i	30	

M. Sig.: At one dose and repeat every four hours.

Medicolegal

Admissibility of Evidence from Operation After Trial.—The Supreme Court of Kansas says that the case of Bousman vs. City of Stafford was brought to recover damages for injuries received in a fall caused by a defective sidewalk. The jury found against the plaintiff, perhaps as the result of a belief that his injuries were purely imaginary. As alleged by him, they were internal, and of such a character that their existence and origin could at the time of the trial only be shown by his own statements and by the opinions of medical experts. The trial was ended May 27. On June 26, but at the May term of court, the plaintiff filed a motion for a new trial on the ground of newly discovered evidence, the character of which was not stated in the motion. In support of this motion, which was heard at the next term of court, in October, there was introduced an affidavit of a surgeon stating that on August 12 he operated on the plaintiff, opening the abdomen, and found that, as the result of an injury, an intestine had been ruptured and an abscess had formed, from which various complications had ensued. The pertinence and importance of this evidence were not disputed, but the city contended that it was not sufficient to require the granting of a new trial, because it was merely cumulative. The court, however, does not think so. It says that the physicians could only give their opinions as experts on a matter necessarily involved in some doubt. The surgeon told of a plain physical fact, about which there could be no mistake. His evidence was not of the same character as theirs, and was not merely cumulative to any of it. In other words, the court holds that the testimony of a surgeon that, in the progress of an operation involving the opening of the abdomen of a patient, he found an intestine ruptured, is not merely cumulative to that of a physician that on an external examination he concluded that such a rupture probably existed. Nor does the court agree with the objection made to the granting of the motion for a new trial that the court had no right to consider the affidavit of the surgeon, for the reason that it related to a fact that was not known to the plaintiff and could not have been known to any one at the time the motion for a new trial was filed. It holds that, on the hearing of a motion for a new trial on the ground of newly discovered evidence, the inquiry is not limited to matters known to the applicant or within his contemplation when the motion was filed, but may include, as well, any that have been developed since that time. Wherefore, it ordered a new trial.

Practice of Medicine by Corporations.—The Supreme Court of Nebraska says that it was contended in State Electro-Medical Institute vs. State that said corporation had violated Chapter 55 of the Compiled Statutes of Nebraska of 1901, which is "An Act to Establish a State Board of Health, to Regulate the Practice of Medicine," etc. The particular provision which it was claimed had been violated was the one in Section 7: "It shall be unlawful for any person to practice medicine, surgery or obstetrics or any of the branches thereof, in this state, without first having applied for and obtained from the State Board of Health a license so to do." And the Supreme Court holds that, while a corporation is in some sense a person and for many purposes is so considered, yet it is not such a person as can be licensed to practice medicine. This corporation, therefore, not having a license, violated this law, if it practiced medicine, surgery, or obstetrics, or any of the branches thereof, within the meaning of the statute.

The statute, in Section 17, the court goes on to say, attempts to define what is meant by "practicing medicine:" "Any person shall be regarded as practicing medicine, within the meaning of this act, who shall operate or profess to heal or prescribe for or otherwise treat any physical or mental ailment of another." Exception is made of the "administration of ordinary household remedies" and in some other cases. The Supreme Court of Kansas has said: "The practice of medicine may be said to consist in three things: First, in judging the nature, character, and symptoms of the disease; second, in determining the proper remedy for the disease; third, in giving or prescribing the application of the remedy to the disease." Underwood vs. Scott (Kan.), 23 Pac. Rep., 942. There was no necessity of legislation to prohibit corporations, as such, from practicing medicine. It is impossible to conceive of an impersonal entity "judging the nature, character and symptoms of the disease," or "determining the proper remedy," or giving or prescribing the application of the remedy to the disease. Members of the corporation, or persons in its employ, might do these things, but the corporation itself is incapable to do them. The qualification of a medical practitioner is personal to himself. The intention of the law is that one who undertakes to judge the nature of a disease, or to determine the proper remedy therefor, or to apply the remedy, must have certain personal qualifications; and if he does these things without having complied with the law he is subject to its penalties. Making contracts is not practicing medicine. Collecting the compensation therefor is not practicing medicine within the meaning of this statute. No professional qualifications are requisite for doing these things.

In other words, the court holds that qualified and licensed physicians may form a corporation and make contracts for the services of its members and other licensed physicians. Making such contracts and furnishing services of qualified and licensed physicians thereunder is not a violation of said Section 7 forbidding the practice of medicine without a license.

It was urged that no one not himself licensed to practice can be beneficially interested in the practice of medicine, and that it is contrary to public policy, and therefore unlawful, for a person or corporation not competent to practice medicine to be beneficially interested in such practice and to be allowed to receive compensation for the services of one who is qualified. For the discussion of this question the court refers to the companion case of State Electro-Medical Institute vs. Platner, decided the same day, which, however, is "not to be officially reported," but may be found in the advance sheets of 103 Northwestern Reporter, 1079. In this latter case the court says that the construction that no person may profit by or enforce an agreement for the practice of medicine, except he is qualified and licensed for the practice of the profession, would prevent action in the name of any assignee of a physician's claim for his services, whether such assignee might be a corporation, a copartnership, or an individual.

Again, the court says that a hospital which is controlled by a corporation, and which receives patients, and contracts to care for them and to furnish them with medical attendance, does not, by so doing, practice medicine within the meaning of this act. Whether a physician who allowed a corporation to make contracts for his services such as he might not make, or who associated himself with and practiced in pursuance of contracts made by corporations that indulged in conduct that would be unprofessional if done by a physician, might himself be made responsible for these acts of the corporation, and so subject himself to the penalties of this act, it was not necessary in this case to decide. The contract in question was signed by the "Physician in Charge." He woud seem to be as much responsible for this contract, and his own action under it, as if he had executed the contract in his own name. Would the same be true of any physician who, being in the employ of the corporation, should practice medicine pursuant to this contract? The court passes this question also without an answer in this case. If further legislation is necessary to regulate and control the conduct of such corporations, and of physicians connecting themselves with such corporations, the argument, it says, should be addressed to the Legislature. The court can not derive such legislation from any public policy indicated by the provisions of this act.

It was further suggested that one of the grounds for revoking the license of a practicing physician is unprofessional conduct, in the betrayal of professional secrets, and that there is no restriction on a corporation that might obtain such secrets and betray them. The court answers that such secrets are imparted for the purpose of enabling the physician who treats the patient to understand the nature of his disease and to determine the best course of treatment. No self-respecting physician would encourage the curiosity of his clerks or assistants in attempting to discover the secrets of his patients; and if he participated in such conduct, or knowingly consented to its exercise, he might furnish grounds for the revoking of his license. If the patient saw fit to divulge his secrets to the assistants or agents without the knowledge of the physician, he would be supposed by so doing to indicate his willingness that they be published to the world.

6 Hematoma of [illegible] L. Manasses, Philadelphia.

1. Epigastric Linea Alba Hernia.—The importance of this hernia as a source of gastric symptoms, says Stewart, has received too little attention from physicians. These hernias are small, sometimes barely perceptible to the eye, and in other instances fairly evident on inspection. Symptoms are usually referred to the stomach, whence a diagnosis of some form of gastric disorder, gastritis, gastralgia, and even gastric carcinoma or gallstone may be made by the unwary. The apparent triviality of the protrusion, even if it does not escape recognition, often does not suggest itself to the physician as a likely source of the malady.

2. Phthiriasis.—Knott has made the occurrence of some striking cases of phthiriasis in his practice the nucleus of an extremely interesting and exhaustive account of the various aspects of this condition. This disease (morbus pediculosus vel pedicularis) has figured more largely than probably most readers are aware, not only in clinical history, dermatology and pathology, but in general phrase and fable, in political history, in imperial and ecclesiastical biography, in orthodox theology, and in the endless mazes of heathen mythology. Knott's paper contains the principal available items from all these sources of information—and imagination, and offers interesting as well as instructive reading. Some of the pedicular lore is certainly very fantastic, and throws a strange light on some of the byways of human thought. In his concluding sentence he offers "the opinion that the scientist who succeeds in plucking out the heart of the mystery of the triplex 'natural selection' topographically displayed in the life history of human pediculi will have done more toward establishing a true theory

of parasitic and infectious disease than has hitherto been reached by bacteriologic pathology." This statement of opinion implies that the writer is not satisfied with the "germ theory" as understood at present.

7. Pulmonary Tuberculosis; Clinical Suggestions.—Loomis presents the results of careful clinical study of 500 cases of pulmonary tuberculosis which illustrate the disease in all its phases as occurring in every walk of life. In 80 per cent. of 100 selected cases the first presumable evidence of the disease was as follows: In 48 per cent. the first symptom of any pulmonary trouble was a cough which ran for weeks or months. In 20 per cent. of these cases the cough was not accompanied by any expectoration. In 18 per cent. the first evidence of disease was loss of flesh, associated with a general "run down" condition. Sixteen per cent. of the cases gave a definite history of having had at some time one or more attacks of pleurisy, from which they recovered, and which were followed by periods of perfect health. The average length of time which elapsed between the first attack of pleurisy and the actual development of the disease was three and a half years. In the first two groups the average time the condition lasted before the disease developed was five and one-half months. In the remaining 20 per cent. of cases the pulmonary condition followed grippe, malaria, pneumonia, enlarged lymph glands, and hemoptysis. Loomis is convinced that the great majority of patients who apparently develop pulmonary tuberculosis after 30 years of age have had an attack of the disease before; often so slight that it was overlooked, or they recovered so rapidly, owing to climatic advantages, that they questioned whether they ever had it, and unless a very careful history is obtained, the fact is never mentioned, or is overlooked, and the condition for which they come under observation is believed to be the beginning of their pulmonary trouble. Among the features of value in making a prognosis are the general vitality of the patient, his personal and family history; age (between 25 and 30 being especially favorable); character, intelligence, and disposition of the patient; condition of the digestive functions. Whether one lung or more than one is involved does not seem to be a very important element in prognosis. Fever, hemorrhages, expectoration and tubercle bacilli in the sputum are of little value in prognosis. An analysis of 55 "cured" sanatorium cases showed that the average age was high—29, and that the long-lived ancestry of the patient was of special importance; whereas a tuberculous family history was of less importance. The average length of life among the tuberculous poor, with no advantages of rest or good food, is a little under two years.

8. Suggestion for Reducing Summer Diarrhea in Infants.—Southworth says that suitable prophylactic measures should date from the birth of the child, and one of the most important is breast nursing. If the secretion of milk be scanty, it should be used for part of the feedings at least, and every effort should be made to encourage the flow. Errors in weaning, neglect of apparently mild attacks of diarrhea, and the common diagnosis of teething used as an excuse for any evidence of illness are factors that must be combated. Only through personal, painstaking instruction of the masses can the desired end be accomplished.

9. Feeding in Typhoid.—Nichols urges that typhoid patients should be given a more varied and more abundant diet than is now customary. He takes the ground that the adoption of milk as the chief article of food for such patients has no logical justification. While it is a complete food for infants, it is not adapted for the exclusive nourishment of adults, except in amounts that are practically prohibitive. The present method of feeding in typhoid has developed in a way that seems largely empirical, and the history of the dietetic treatment of fevers, which is reviewed in full by Nichols, shows a progressive advance from a starvation regimen in the direction of a more and more liberal diet.

10. Animal Remedial Preparations.—Wainwright contributes an exhaustive paper on the various glandular and other animal extracts which have lately come into use in therapeutics.

11. Hypodermic Use of Salicylate of Mercury in Syphilis.—Kilbane recommends this treatment for trial in every case of syphilis in which the administration of mercury is indicated for a long period of time.

14. Bacterial Content of Railway Coaches.—Kinyoun details the experiments conducted by him for the purpose of determining the bacteriology of railway coaches. The only fact which seems to have been proved in this investigation was that 73 per cent. of the animals inoculated with material taken from the coaches gave only negative results, thus demonstrating that the bacterial content of the railway coach, in the majority of instances examined, was not infectious to animals.

14½. Cure of Leprosy.—Dyer believes that leprosy is curable in the same sense that syphilis and tuberculosis are curable. No patient treated by him has failed to respond to the treatment; amelioration occurs invariably, and when treatment has commenced early enough and has been kept up long enough a certain number of patients have recovered. The only remedies giving results were strychnin, antivenomous serum, chaulmoogra oil, and chlorate of potash. He believes that the oil more nearly approximates a specific for leprosy than any treatment as yet suggested. Full diet, restricting only indigestible foods, is indicated. The disease seems in no wise to be affected by fish or any other particular article of diet. Baths are essential in the treatment. Hot baths twice a day, with or without soda, are effective. The patient needs tonics and febrifuges, and should be watched for intercurrent or complicating diseases, such as malarial infection, pleurisy, pneumonia, grippe, and the like. Strychnin is a *sine qua non* in the treatment of leprosy. A leper should always take strychnin. When chaulmoogra oil is given, it is better endured before meals than after. It is best taken in capsules, in hot milk, or in milk of magnesia. The dosage should be small at first, say 3 drops, and increased every second or third day until from 120 to 150 drops of the oil are taken at the dose. At times it is advisable to give the oil in pill form. This can be done by combining it with extract of nux vomica and ordinary excipients, or, a very effective way, with tragacanth and common soap. Above all things, individualize the patient. Watch for improvement, and if it does not show in three months wait six months—if it does not show in six months, wait a year, or longer. But keep on driving at the treatment until the patient dies or gets well. Dyer has on record one patient who did not show any signs of improvement for two years, but who is now well. When all evidences of the disease are gone, insist on a continuance of treatment. It may not be necessary, but it makes sure.

17. Lavage with Siphon Tubes and Politzer Bulbs.—Sawyer favors the use of the simple Politzer bulb with the glass connection fitting into bulb and tube. The food residue having been aspirated as completely as possible with an empty bulb, a bulbful of solution, medicated as desired, is introduced slowly into the stomach, and free, active manipulation of the anterior abdominal wall over the region of the stomach is used with sufficient energy, sometimes also shaking the posterior surface of the stomach, especially in conditions of atony or ectasia without ptosis. By this is produced a considerable movement of the liquid within the stomach useful for thorough cleansing and bringing the drug in close contact with the cleansed membrane. Then Sawyer allows the contents to be withdrawn in the aspirator which has been controlled by pressure with the hand till this time, and cleansing of the viscus can be accomplished more thoroughly, in less time, with less fatigue to the patient, than can be accomplished by the use of the siphon tube. That the whole quantity used as a wash is withdrawn is seen by the filling of the bulb. The patient is freed from efforts at expression, and lying as quietly relaxed as possible gains much in comfort. Sawyer draws especial attention to the advantage in lavage of having the patient reclining with loosened clothes, and then making use of free manipulation of the stomach wall to secure a more thorough cleansing and the more thorough application to the mucous membrane of suitable solution chosen for direct medication. In this fashion all the solutions used may be employed with a reasonable certainty that all portions of the stomach membrane are reached in the treatment and that all of the solutions injected are withdrawn.

19. **Fractures and Their Treatment.**—Cotton presents a general review of the treatment of fractures and lays special stress on the following points: (a) A better recognition of the advantage of early mobilization will give better functional results. (b) A review of position (with *x*-ray, if possible) should be a routine at a time when correction is still readily possible by open if not by closed methods. (c) Many bad end-results of fractures are remediable by operation; such operations under proper conditions are devoid of any considerable risk, and the field for such corrective operations has increased and is still increasing with greater experience and wider knowledge of the results obtainable.

20. **Spinal Surgery.**—In the first of the two cases reported by Walton and Paul the clinical picture was that of severe pain in the neck and arm, accompanied by local wasting, numbness and loss of power in the arm, and by rigidity of the neck. Operation disclosed a myeloma involving the laminæ and pressing on the dura in the lower cervical region; its removal was followed by relief of pain and rapid improvement of motor and sensory symptoms. In the second case, pain centering in the right arm, accompanied by a modified Brown-Séquard paralysis of gradual onset and rapid progression, led to the diagnosis of tumor pressing on the cord unilaterally in the lower cervical region. Removal of the vertebral arches failed to disclose the tumor, which on autopsy was found to project posteriorly from the anterior wall of the spinal canal at the level of operation. The authors believe in giving the benefit of the doubt to operation in all these cases, for the following reasons: First, there is the bald fact that without interference a hopeless prognosis must be given; second, in ruling out operation, the patient and the family are refused a legitimate attempt to ameliorate discomforts if not to effect a cure; third, if out of many operations, one only is successful, the result, it seems to us, justifies the endeavor; fourth, if selected patients only are operated on, there is great danger that the present limitation of our diagnostic criteria would cause us to overlook the case in which operation would have been most brilliantly successful.

23. **How to Palpate a Movable Kidney.**—Aaron says that bimanual palpation is always necessary in palpating a movable kidney. The hand over the lumbar region forces the organ forward, while the hand on the abdomen gently presses toward the hand on the back. It must be remembered that firm pressure is the rule for the hand on the back. To palpate for a movable kidney, he usually places the patient in four different positions: 1. Standing, while manipulator sits on a chair. 2. Standing, while manipulator stands. 3. Lying on back, while manipulator sits on edge of couch. 4. Lying on either side, depending on kidney palpated, while manipulator is sitting.

24. See abstract in Journal, July 8, 1905, page 128.

25. **Simulation of Appendicitis by Cholelithiasis.**—Lempe reports a case of cholelithiasis which previously had been diagnosed as appendicitis and was treated as such.

26. **Lithemic Gangrene.**—Rosewater reports the case of a man, aged 64, emphysematous, rheumatic, suffering with asthma and bronchitis, with a history of superficial gangrene, who was treated for gangrene of the anterior right tibial surface by elevation, antisepsis, heat and a lacto-cereal diet. He was discharged, cured, in six weeks, but was advised to continue the diet. Every indiscretion in eating was followed by some disturbance, such as pruritus and gangrene. On strict observance of the diet he remained well. The author believes that the history of this case, lithemic stigmata, deviation from normal each time uric acid or purin food was added (each time only one incriminating article) and the patient's return to and maintenance of normal health when strictly on the diet is as diagnostic of lithemia and as justifiable as would be potassium iodid and mercury for lues.

34. **Freak Case of Appendicitis.**—The case reported by Nichols presented the usual symptoms of an attack of appendicitis—the catarrhal variety. Calomel and a saline were ordered, and the patient improved considerably, so that the operation which had been arranged for was postponed. One week after the beginning of the attack, the patient passed a very restless night, complaining of discomfort and tenesmus. In the morning there were several loose stools, one of them containing a very much attenuated appendix about two and a half inches long, with a perforation at the distal end. After his auto-operation, the patient made a rapid and uneventful recovery. Microscopic examination of the tissue showed it to be the appendix, but *it was absolutely necrotic.*

43 Etiology and Pathology of Gastric Ulcer. J. McFarland.

38. **Rectangular Flaps for Transference with Pedicle.**—Babcock's method consists in forming two rectangular flaps, having a width at least one-third wider than the part to be covered, and a combined length about one-third greater than the greatest diameter of surface to be covered. These are formed

in the following manner: A straight incision is made equal to the combined length of the flaps to be raised. Parallel to the first incision and at a distance equal to the width of each flap to be formed, two secondary incisions, one on either side of the original incision, are made. On one side a second incision is placed opposite the upper half of the first incision, while the third incision is made on the other side of the first incision and parallel to its remaining half. By uniting the distal ends of the last two incisions with those of the first, two flaps are formed, which are then raised, leaving two lines of parallel and equidistant wound edges. These are then united in a linear manner, the bases of the flaps being slid by each other until they become exactly opposite. There now remain two linear incisions, at the proximal ends of which are attached the bases of the two flaps with raw surfaces outermost, ready for attachment to the surface to be covered. These surfaces are prepared for grafting in the usual manner, and the limb with the grafts is superimposed on the surface to be covered. The grafts are then fastened to their new position by interrupted or continuous sutures, and the folds at the pedicle of the grafts protected from angulation and pressure by properly applied padding of sterile gauze. At the end of from five to ten days, when the grafts have acquired a sufficient circulation from their new bed, the two pedicles are divided and the limbs separated, leaving a short transverse incision on each limb. It is important that the retentive dressing affords absolute support, so that there be no undue pressure between the opposing surfaces, and that adequate fixation, absolutely preventing any displacement, be provided.

44 Time as an Element in Abdominal Surgery. M. H. Richardson, Boston.
45 *Subparietal Injuries of the Abdomen. C. J. Holman, Mankato.

45. Subparietal Injuries of Abdomen.—Holmes says that it would seem as though, with a patient, who had received a severe blow in the abdomen, having pain and tenderness on pressure, and with rigidity or spasm of the abdominal muscles, exploration should be advised. If the patient should survive the traumatic peritonitis, there would still be cicatrices and adhesive bands that would require subsequent repair. The degree of violence of the vulnerating body is not necessarily in proportion to the injury produced, because Nature has many means of protecting the abdominal viscera. If the surgeon waits for positive symptoms of hemorrhage and infection, the exploration will be too late and useless. Since the introduction of modern methods in the treatment of shock, i. e., salt solution, hot water, operating tables, etc., speed is not of as great moment as thorough work.

47 *Trichorrhexis Nodosa. M. L. Heidingsfeld, Cincinnati.
48 Creeping Eruption. J. B. Shelmire, Dallas, Texas.

47. Thichorrhexis Nodosa.—Heidingsfeld reports one case of this affection. He says that it is universally present in long, uncut hair as a normal condition and is probably Nature's method of physiologically arresting and stunting an otherwise unlimited and eventually cumbersome overgrowth of hair. When present to excess in a predisposed individual, it becomes a pathologic process and abnormally stunts the growth of hair; the nodes are more prominently wounded and are often multiple, separated from each other by uniform intervals of normal hair shaft. Its etiology has been variously attributed to trophic, parasitic and mechanical influences. A mechanical causation is improbable on purely clinical grounds, and it is incapable of artificial demonstration. The condition in brushes can likewise not be attributed to purely mechanical causes. A parasitic causation is not commensurate with the evidence thus far adduced from clinical studies and bacteriologic investigations. The most rational explanation of its etiology from physical, bacteriologic and clinical investigations, and its analogy to kindred and associated changes in the hair rests in trophic influences, emanating from the metabolism at large, and permeating the hair to its ultimate extent.

52 Synesthesia. H. L. Smith, Baltimore.

51. Congenital Urethral Stricture Suggesting Renal Disease.—The interesting features of the case reported by Churchman can be summarized as follows: The patient presented a urethral stricture in which a positive diagnosis of its congenital nature could be made. Such a diagnosis was warranted by: (a) The history, from which all record of urethral traumatism or of venereal infection was absent. (b) The association of an obvious congenital stricture at the meatus. (c) The complete cure of the clinical manifestations by proper treatment of the stricture. (d) The presence of clear urine and the absence of symptoms after the actual stricture had been dilated. The second point of interest was offered by the clinical symptoms presented. These were nausea and vomiting, hematuria, and pain over the left ureter. They suggested renal or urethral disease, and obscured the diagnosis which was really only cleared up by the therapeutic test. In the third place, this case suggests that another item must be added to our already long list of causes for hematuria, and that congenital stricture may be associated with blood in the urine, the source of which may probably be an hypertrophied verumontanum.

53. Submucous Resection of Cartilaginous Septum.—The essential feature of this operation is the instrument used in its performance—the swivel septum knife—devised by Ballenger. The swivel blade of the knife is pivoted to the extremities of the tuning-fork-like prongs of the instrument and swings in a circle. By the resistance of the cartilaginous tissue through which the knife passes, it may be made to cut in any direction in which the distal ends of the prongs are directed. If the prong tips are made to describe a perfect circle, the blade will follow and excise a circular disc of cartilage. The technic of the operation performed by Ballenger is after the Menzel-Hajek method, with the exception of the removal of the cartilage, which is removed in one piece with one cut of the swivel knife. Using a special mucosa knife devised by himself, Ballenger makes a curved incision in the septal mucosa about one inch in length, beginning near the floor of the nose and curving forward and upward as high as possible through the vestibule of the nose and about one-fourth inch posterior to the anterior margin of the cartilage. The incision is made on the left side of the septum, regardless of whether this be the convex or the concave surface, because it is convenient to use the knife with the right hand while the forefinger of the left is inserted into the right nostril. Having made the curvilinear incision through the muco-perichondrium, he resorts to the semi-sharp elevator of Hajek to elevate the anterior portion of the muco-perichondrium from the septum, after which Hajek's blunt elevator should be used. With a bistoury the incision is carried through the cartilage to the perichondrium of the opposite side. The perichondrium is lifted from the cartilage and the prongs of the swivel knife are then introduced through the incision. The instrument is directed backward, parallel with the floor of the nose, until the posterior limit of the cartilage is reached, when it is directed upward and forward, following the outline of the anterior end of the perpendicular plate of the ethmoid to the bridge of the nose, when it is pulled downward, parallel with the bridge of the nose, to the upper extremity of the curvilinear incision. In this way almost the entire septum is removed, except the anterior tip which is to support the tip of the nose. The excised cartilage is removed with a pair of dressing forceps. This method is simple, is devoid of traumatism and shock, can be done in a few seconds, will not result in laceration or perforation of the muco-perichondrium, and the entire cartilage can be removed in one piece, being available for thorough inspection.

57. **Galvano-cautery in Nasal Affections.**—Anderson protests against the use of the galvanocautery as a routine measure in the treatment of nasal diseases. In cases where there is an engorgement of the turbinal, and where under cocain the tissue shrinks to a marked degree, submucous puncture is a simple and efficacious method of treatment. In true hypertrophy, when simple submucous puncture is not sufficient, the flap operation is most satisfactory. The use of the cautery for severing adhesions or false membranes can be discarded and better results obtained by making flaps of tissue to cover the denuded surface, thus preventing the formation of synechiæ. Rather than to cauterize the base of polypi, it is better to curette thoroughly. In cases of hemorrhage from the nose it is better to apply adrenalin, and then to pack the nose carefully with subnitrate of bismuth lint, than to use the cautery. In the treatment of hypersensitive areas in the nose in certain neuroses of nasal origin the cautery has a place, but even here it should be used carefully. The aim should be always to destroy as little mucous membrane as possible, to avoid the formation of adhesions, and the occurrence of ulceration.

63. **Safe Method for Opening Retropharyngeal Abscesses in Children.**—To overcome the time element and to make an adequate opening for free drainage, Meierhof recommends the use of a pair of dressing forceps of the length best suited to free manipulation and which are bent on the flat, with the beaks somewhat curved and moderately pointed. The child is seated in an upright position on the knee of an assistant, who places one hand on the child's forehead and encircles its arms and body with one arm. The moment the abscess is entered with the forceps the assistant throws the child's head and body forward; while in this position the forceps are withdrawn with the blades open, thus allowing the abscess to be thoroughly evacuated and good drainage established.

102 Metastatic Car Body. G. W. Cutler, New York.

98. **Caffein in Quinin Amblyopia.**—The special interest in the case reported by Schwabe lies in the influence which may be exercised by caffein on the field of vision. The conclusions to be drawn from his observations are, in the first place, that amaurosis with a concentric contraction of the visual field persisting for over a year, hemeralopia, and great narrowing of the retinal arteries can be caused by a dose of quinin hitherto judged to be harmless (1.25 g.) in an apparently healthy person with a relaxed vascular system, whose power of resistance has been reduced by insufficient nourishment, and, in the second place, that in such a person caffein, also in small doses (0.1 g.), can temporarily induce a further contraction of the retinal vessels and of the peripheral field, without either influencing the central vision and color perception, or causing a permanent injury to the peripheral vision in spite of frequent repetition for a year.

99. **Vernal Catarrh.**—Falta directs attention to the possibility of mistaking vernal catarrh for trachoma, and describes ollowing forms of the disease: 1. The eye shows no , except a slight ciliary injection. The patient has photophobia. It is the initial stage of the disease, but lly of brief duration. The diagnosis is very difficult. 2. form the most typical and also the most common, observed degeneration of the tarsal conjunctiva of the d, which presents the appearance of a stone pavement. tiva of the lower lid is catarrhal, or only hyperemic. m is often mistaken for trachoma. 3. About the cornea nish nodules which sometimes cross the margin and the cornea itself. A network of conjunctival vessels is d to each nodule. There is more or less photophobia, ntly hyperemia of the iris with ciliary injection and onally hyperemia of the palpebral conjunctiva. This may be mistaken for phlyctenular keratitis or keratitis ulosa. 4. This form is characterized by flat, broad infilons of colloidal consistence in the ocular conjunctiva with vascular networks attached. It may be confounded with leritis. 5. A mixture of the second and third varieties. 6. ixture of the second and fourth varieties. Although the osis of vernal catarrh is usually easy, a great help in osticating the condition is the fact that if the diseased s rubbed quickly and gently with the upper lid, or if, eversion of the lid, the proliferations on the tarsal surf the conjunctiva are rubbed with a little glass rod, the nt will complain of severe itching. This happens with no disease. In the summer, he sends the patients to a cool tain resort. For those who can not go to such a place he dark glasses and the constant application of cold coms, which render the disease much more endurable during arm months. In addition, every second or third day he the upper lid and massages the conjunctiva with yellow ent on a small glass rod, and then massages the nodules nfiltrates by means of the lid itself.

8 *Treatment of Serous Effusions by Injection of Adrenalin Chlorid. H. W. Plant and P. Steele.

1. **Prospects and Vicissitudes of Appendicitis.**—A review of statistics on the subject of appendicitis by Ballance gives the following results: 1. A certain proportion of cases recover without surgical intervention, and of these some remain for a considerable time, if not permanently, free from relapse. The proportion of such cases varies considerably in different series, even when treated by observers whose plan of treatment is identical 2. The mortality of late operations is high, and that when it is found necessary to operate after failure of other treatment the condition found is almost invariably such as would have been better and more easily dealt with by an earlier operation. 3. The rule to operate early in all cases leads to the recovery of a large proportion of the severe cases. 4. The appendix may be safely ablated, even when localized abscess is present. 5. The statistics of those adopting the opportunist rule seems always charged with at least a small number of cases in which it would seem probable that life might have been saved or an undesirable complication avoided by early intervention. 6. A large proporti
cases
with diffuse peritonitis are first attacks
ever, that: 1. Every diagnosable infla
signs of increasing local or general periton
moved. 2. Every appendix which has given r
tion or abscess should be removed. 3. In serio
it is unwise to leave the appendix; as the prima

fection is more likely to cause the continuance of constitutional symptoms than the spreading peritonitis around. Further, if left it requires another operation for its removal.

3. **Acute Salpingitis.**—Bland-Sutton refers to a case in which an inflamed appendix perforated, and the inflammatory products were discharged into the right Fallopian tube through its fimbriated extremity.

8. **Serous Effusions Treated by Injection of Adrenalin Chlorid Solution.**—In all the cases in which Plant and Steele have tried the effect of the injection of adrenalin, the following has been the method adopted: As much as possible of the fluid was withdrawn by a two-way trochar and cannula, and through the cannula, still *in situ*, a dram of adrenalin chlorid (1 in 1,000), diluted to ½ oz. with sterile water, was introduced by means of an exploring syringe. The cannula was then removed, the wound closed with wool and collodion, and, in abnormal cases, the abdomen was gently manipulated for five minutes and a binder firmly applied. The only cases of ascites, with one exception, in which adrenalin was tried were those due to cirrhosis of the liver, and without exception the treatment proved successful. Immediately after the injection in ascitic cases the patients often complained of sharp abdominal pain. In all cases there was a rise of from 0.5 degrees to 2 degrees of temperature, occurring usually within half an hour of the time of injection, also an immediate rise in the pulse tension was noticed lasting from a quarter to half an hour. In no case was the amount of urine altered.

aged 45, seen after the birth of the first child, in January, 1897, made a good recovery. The remaining 20 were ascertained to have died as follows: two at the end of one month, two at 2 months, one after 3 months, two after 4 months, one after 5 months, one after 6 months, two after 9 months, one after 12 months, one after 15 months, one after 22 months, two after 24 months, one after 28 months, two after 32 months, and one after four and a half years. The average duration of life in these cases is 14½ months. Snell concludes that the appearance of changes in the retina is an indication of the systemic havoc wrought by the nephritis, and that it portends a fatal termination, which may occur in a few months, and is rarely delayed longer than two years.

Journal of Tropical Medicine, London.

23 Large White Kidney. G. Peacocke.
24 Two Cases of Endometritis, with Remarks on Treatment. R. D. Purefoy.
25 Treatment of Diphtheria. C. H. W. McCullagh.

22. **Clinical Report of Rotunda Hospital.**—Tweedy reports 1887 cases of labor in the hospital, with a mortality of 8.42 per cent. Thirteen women died throughout the year. Premature labor was induced five times. There were 13 cases of accidental hemorrhage, one ending fatally. Nine of these patients required no treatment; in the others, labor had not commenced, and in these, moist aseptic pellets of cotton wool were packed tightly round the cervix and promptly checked the hemorrhage. There were 4 cases of placenta prævia, with one death due to septic infection, which existed when the patient entered the hospital. Bi-polar version was performed in the remaining cases, and in one a living child was born. Twenty-nine cases of postpartum hemorrhage were treated successfully by massage, ergot, hot vaginal douches and plugging the uterus with sterile gauze. Manual removal of the placenta was performed 36 times. In 6 cases postpartum hemorrhage was the indication, while in 31, adherent placenta was present, and in 5, retention was due to spasms of the uterus. Eight patients developed eclampsia—five primipara, two II-para and one III-para. In two the convulsions occurred postpartum, and in two others they occurred both before and after delivery. Macerated children were born in four of the cases. Prolapse of the funis occurred in seven cases, as did also hydramnios. Hyperemesis gravidarum occurred once, a severe case, which was relieved by feeding the patient for three days per rectum and by administering numerous saline enemata. Mania of mild type developed in two cases, both primipara. Symphysiotomy was done once for short internal conjugate. Cesarean section was performed once, both mother and child surviving. Craniotomy was necessitated in the case of a dead child with prolapsed non-pulsating cord. There were 61 cases of abortion and immature delivery. In 31 of these the uterus was emptied of its contents by natural methods. In 6 bi-manual expression sufficed to remove the ovum, while in 12, fingers inserted into the uterus caused complete separation of retained contents, and these were subsequently expressed bi-manually or removed by ovum forceps. In 8 cases, the cervix being narrow, a flushing curette was employed to empty the cavity. In one, replacing a retroflexed uterus and flushing out its cavity caused the ovum to escape. In the remaining two cases the cervix was dilated by Bossi's dilator to extract immature fetuses. Three cases of hydatidiform mole occurred, one of them subsequently developing a chorioepithelioma. Of three cases of hematoma of the vulva, only one necessitated opening the tumor and turning out the clots. There were ten cases of podalic version, 392 cases of lacerated perineum, and 65 forceps cases. Among the infantile conditions were the following: Hydrocephalus, 5 cases; spina bifida, 6 cases; meningocele, 2 cases; imperforate anus, 4 cases; cleft palate, 2 cases; icterus, 9 cases; and anencephalia, 3 cases.

27. **Rapid Microscopic Diagnosis.**—Wederhake describes a technic which stains fresh specimens so rapidly that the diagnosis can be made in five minutes from the time the specimen is obtained. It can be used to stain the sediment of urine and other fluids. The technic is extremely simple and practicable, differentiating distinctly almost all kinds of cells, including plasma cells, giant cells, muscle cells, certain cocci and even fat on a larger exposure. If the results are not satisfactory, or to control them, the stain can be washed away with diluted ammonia and any other stain then used. The fresh frozen section is taken up, without rinsing, in tincture of iodin (2 to 5 drops in 20 c.c. of water). The section is then transferred, without rinsing, to a 20 per cent. dilution of a stain made by dissolving crocein scarlet 7 B in 10 c.c. of 700 per cent. alcohol until the alcohol will not dissolve any more. It does not take up much. After from one-half to three or five minutes in the stain, the specimen, still held on the spatula, is rinsed and soaked in water for a minute or two—five minutes would probably dissolve out all the stain. The specimen is then allowed to slide off the spatula into a drop of glycerin on the object glass, when it is ready for the microscope after being covered with a cover glass. If the specimen is already fixed, it has to be soaked for two hours in 40 per cent. formalin, and then rinsed in water for two hours, after which the technic is the same as for fresh specimens.

29. **Disinfection of Abdominal Walls.**—Saniter urges the adoption in Germany of the French method of inverting the umbilicus to disinfect it properly before a laparotomy. The center is seized with small forceps and drawn outward, which smooths out the folds and allows the dirt of decades to be readily washed away.

32. **Extramedian Symphyseotomy.**—Two cases treated by Gigli's lateral section of the pubis are related by Bürger and two more by Küttner, the latter the first in Russia. The subcutaneous technic, without drainage, is proving most satisfactory. The operation is so simple and the results so universally good, that both writers believe that pubiotomy is destined to supplant Cesarean section and to abolish perforation of a living child, and also to take the place of prophylactic version in some cases. The bone should be sawed on the smallest side of the pelvis or nearest the fetal occiput.

8 *Treatment of Serous Effusions by Injection of Adrenalin Chlorid. H. W. Plant and P. Steele.

1. Prospects and Vicissitudes of Appendicitis.—A review of statistics on the subject of appendicitis by Ballance gives the following results: 1. A certain proportion of cases recover without surgical intervention, and of these some remain for a considerable time, if not permanently, free from relapse. The proportion of such cases varies considerably in different series, even when treated by observers whose plan of treatment is identical 2. The mortality of late operations is high, and that when it is found necessary to operate after failure of other treatment the condition found is almost invariably such as would have been better and more easily dealt with by an earlier operation. 3. The rule to operate early in all cases leads to the recovery of a large proportion of the severe cases. 4. The appendix may be safely ablated, even when localized abscess is present. 5. The statistics of those adopting the opportunist rule seems always charged with at least a small number of cases in which it would seem probable that life might have been saved or an undesirable complication avoided by early intervention. 6. A large proportion of the bad cases with diffuse peritonitis are first attacks. He concludes, however, that: 1. Every diagnosable inflamed appendix with signs of increasing local or general peritonitis should be removed. 2. Every appendix which has given rise to inflammation or abscess should be removed. 3. In serious acute cases it is unwise to leave the appendix; as the primary site of infection is more likely to cause the continuance of constitutional symptoms than the spreading peritonitis around. Further, if left it requires another operation for its removal.

3. Acute Salpingitis.—Bland-Sutton refers to a case in which an inflamed appendix perforated, and the inflammatory products were discharged into the right Fallopian tube through its fimbriated extremity.

8. Serous Effusions Treated by Injection of Adrenalin Chlorid Solution.—In all the cases in which Plant and Steele have tried the effect of the injection of adrenalin, the following has been the method adopted: As much as possible of the fluid was withdrawn by a two-way trochar and cannula, and through the cannula, still *in situ*, a dram of adrenalin chlorid (1 in 1,000), diluted to ½ oz. with sterile water, was introduced by means of an exploring syringe. The cannula was then removed, the wound closed with wool and collodion, and, in abnormal cases, the abdomen was gently manipulated for five minutes and a binder firmly applied. The only cases of ascites, with one exception, in which adrenalin was tried were those due to cirrhosis of the liver, and without exception the treatment proved successful. Immediately after the injection in ascitic cases the patients often complained of sharp abdominal pain. In all cases there was a rise of from 0.5 degrees to 2 degrees of temperature, occurring usually within half an hour of the time of injection, also an immediate rise in the pulse tension was noticed lasting from a quarter to half an hour. In no case was the amount of urine altered.

15 Chemical Mechanism of Gastric Secretion. J. S. Edkins.
16 Strangulated Hernia of the Small Intestine and Bladder. G. F. Barham.
17 Two Cases of Actinomycosis. D. D. Crawford.

9. Tracheal Injection.—Mendel attempts to show that the manipulations required for tracheal injection can be sufficiently simplified to be performed by any physician and without special training, and that the introduction of non-irritating liquids in the air passages never cause any reflex, coughing. or suffocation. One method, the medial, is as follows: If the tongue be protruded and held outside the mouth, the patient not swallowing, the pharynx forms a funnel in which th only inferior outlet is the glottis, the esophagus being closed, s that a small quantity of liquid projected against the posteric wall of the pharynx runs down into the air passages. T [illegible] ond is called the lateral method. In this method the [illegible] must be projected against the lateral wall of the ph [illegible] with sufficient force to turn round this wall and thus [illegible] the posterior wall, whence it falls into the larynx.

11. Influence of Fruit on Precipitation of Uric [illegible] Jerome concludes that pears, fresh figs, grapes, dat [illegible] oranges may be taken not only with impunity but wi [illegible] tinct advantage by those who suffer from uric acid [illegible] and gravel. The beneficial effect, which will be in proportion to the amount taken, is due essentially, if not entirely, to the lessened acidity of the urine. Marmalade does not raise the precipitability of the uric acid, though in the quantity likely to be taken it fails to produce the opposite effect, probably because the amount of fruit pulp is insufficient for that purpose.

14. Duration of Life After Appearance of Alb [illegible] **c Retinitis.**—Of 23 patients traced by Snell three are [illegible] n to be living. Of these, one a man, aged 36, was first [illegible] in July, 1904; the kidney affection had been previously [illegible] nized. Two were women and both had suffered during [illegible] nancy. One, aged 35, seen in March, 1891, recovered [illegible] partially, but became affected again in the next pregn [illegible] two years later, with resulting blindness. The other wo [illegible] aged 45, seen after the birth of the first child, in January, 1897, made a good recovery. The remaining 20 were ascertained to have died as follows: two at the end of one month, two at 2 months, one after 3 months, two after 4 months, one after 5 months, one after 6 months, two after 9 months, one after 12 months, one after 15 months, one after 22 months, two after 24 months, one after 28 months, two after 32 months, and one after four and a half years. The average duration of life in these cases is 14½ months. Snell concludes that the appearance of changes in the retina is an indication of the systemic havoc wrought by the nephritis, and that it portends a fatal termination, which may occur in a few months, and is rarely delayed longer than two years.

Journal of Tropical Medicine, London.

July 15.

18 *Possible Mode of Communication of Leprosy. T. C. Mugliston, Penang.
19 Successful Application of Preventive Measures Against Beriberi. H. Wright.
20 Cerebrospinal Meningitis at Zungeru and Yola in Northern Nigeria.
21 *Obstinate Case of Obstruction of the Bowel—Treatment—Recovery. G. H. Fink, Benares.

18. **Communication of Leprosy.**—For many years Mugliston noted the almost universal occurrence of itch in lepers, and it occurred to him that the disease might be conveyed by the itch mite. On investigation he found that of 77 lepers, 44 had itch on admission; 11 more remembered having had itch, and 22 could not remember.

21. **Obstruction of Bowel.**—Fink cites a case of obstruction of the bowel due to impaction of scybalous masses which was relieved by the injection of 4 drams of glycerin, all other attempts to relieve the condition having failed.

Dublin Journal of Medical Science.

June.

22 *Clinical Report of the Rotunda Hospital. F. H. Tweedy, G. Fitzgibbon and A. Holmes.
23 Large White Kidney. G. Peacocke.
24 Two Cases of Endometritis, with Remarks on Treatment. R. D. Purefoy.
25 Treatment of Diphtheria. C. H. W. McCullagh.

22. **Clinical Report of Rotunda Hospital.**—Tweedy reports 1887 cases of labor in the hospital, with a mortality of 8.42 per cent. Thirteen women died throughout the year. Premature labor was induced five times. There were 13 cases of accidental hemorrhage, one ending fatally. Nine of these patients required no treatment; in the others, labor had not commenced. and in these, moist aseptic pellets of cotton wool were packed tightly round the cervix and promptly checked the hemorrhage. There were 4 cases of placenta prævia, with one death due to septic infection, which existed when the patient entered the hospital. Bi-polar version was performed in the remaining cases, and in one a living child was born. Twenty-nine cases of postpartum hemorrhage were treated successfully by massage, ergot, hot vaginal douches and plugging the uterus with sterile gauze. Manual removal of the placenta was performed 36 times. In 6 cases postpartum hemorrhage was the indication, while in 31, adherent placenta was present, and in 5, retention was due to spasms of the uterus. Eight patients developed eclampsia—five primipara, two II-para and one III-para. In two the convulsions occurred postpartum, and in two others they occurred both before and after delivery. Macerated children were born in four of the cases. Prolapse of the funis occurred in seven cases, as did also hydramnios. Hyperemesis gravidarum occurred once, a severe case, which was relieved by feeding the patient for three days per rectum and by administering numerous saline enemata. Mania of mild type developed in two cases, both primipara. Symphysiotomy was done once for short internal conjugate. Cesarean section was performed once, both mother and child surviving. Craniotomy was necessitated in the case of a dead child with prolapsed non-pulsating cord. There were 61 cases of abortion and immature delivery. In 31 of these the uterus was emptied of its contents by natural methods. In 6 bi-manual expression sufficed to remove the ovum, while in 12, fingers inserted into the uterus caused complete separation of retained contents, and these were subsequently expressed bi-manually or removed by ovum forceps. In 8 cases, the cervix being narrow, a flushing curette was employed to empty the cavity. In one, replacing a retroflexed uterus and flushing out its cavity caused the ovum to escape. In the remaining two cases the cervix was dilated by Bossi's dilator to extract immature fetuses. Three cases of hydatidiform mole occurred, one of them subsequently developing a chorioepithelioma. Of three cases of hematoma of the vulva, only one necessitated opening the tumor and turning out the clots. There were ten cases of podalic version, 392 cases of lacerated perineum, and 65 forceps cases. Among the infantile conditions were the following: Hydrocephalus, 5 cases; spina bifida, 6 cases; meningocele, 2 cases; imperforate anus, 4 cases; cleft palate, 2 cases; icterus, 9 cases; and anencephalia, 3 cases.

27. **Rapid Microscopic Diagnosis.**—Wederhake describes a technic which stains fresh specimens so rapidly that the diagnosis can be made in five minutes from the time the specimen is obtained. It can be used to stain the sediment of urine and other fluids. The technic is extremely simple and practicable, differentiating distinctly almost all kinds of cells, including plasma cells, giant cells, muscle cells, certain cocci and even fat on a larger exposure. If the results are not satisfactory, or to control them, the stain can be washed away with diluted ammonia and any other stain then used. The fresh frozen section is taken up, without rinsing, in tincture of iodin (2 to 5 drops in 20 c.c. of water). The section is then transferred, without rinsing, to a 20 per cent. dilution of a stain made by dissolving crocein scarlet 7 B in 10 c.c. of 700 per cent. alcohol until the alcohol will not dissolve any more. It does not take up much. After from one-half to three or five minutes in the stain, the specimen, still held on the spatula, is rinsed and soaked in water for a minute or two—five minutes would probably dissolve out all the stain. The specimen is then allowed to slide off the spatula into a drop of glycerin on the object glass, when it is ready for the microscope after being covered with a cover glass. If the specimen is already fixed, it has to be soaked for two hours in 40 per cent. formalin, and then rinsed in water for two hours, after which the technic is the same as for fresh specimens.

29. **Disinfection of Abdominal Walls.**—Saniter urges the adoption in Germany of the French method of inverting the umbilicus to disinfect it properly before a laparotomy. The center is seized with small forceps and drawn outward, which smooths out the folds and allows the dirt of decades to be readily washed away.

32. **Extramedian Symphyseotomy.**—Two cases treated by Gigli's lateral section of the pubis are related by Bürger and two more by Küttner, the latter the first in Russia. The subcutaneous technic, without drainage, is proving most satisfactory. The operation is so simple and the results so universally good, that both writers believe that pubiotomy is destined to supplant Cesarean section and to abolish perforation of a living child, and also to take the place of prophylactic version in some cases. The bone should be sawed on the smallest side of the pelvis or nearest the fetal occiput.

33. **Gastric Ulcer in Child.**—Bechtold's patient was a girl of 5. The gastric ulcer terminated in fatal perforation in about five months.

36. **Twenty-six Weeks' Infant.**—The infant born after twenty-six weeks of gestation weighed about 750 gm. (about 24½ ounces) when one month old and when nearly three months old it weighed 1,120 gm. (about 40½ ounces). It succumbed then to a purulent ear affection. It was fed by the bottle very effectively, and during the first seven hours after birth had been exposed to severe chilling.

40. **Muscular System in Rachitis.**—Hagenbach-Burckhardt regards the relaxation and atrophy of the muscles in rachitis as the primary cause instead of the results of the abnormal movability of the joints. When the muscles are strengthened, the flail joints recover normal functioning.

42. *"Gland Fever."—Trautmann does not regard this disease* as a separate morbid entity as some have affirmed.

54. **Rhythmic Movements of Head in Exophthalmic Goiter.**—The rhythmic movements of the head, known as Musset's sign, which have been observed in cases of aneurism, aortic insufficiency and arteriosclerosis, were noticed by Zeither in 4 cases of exophthalmic goiter.

55. **Myasthenia Cordis.**—In the hearts in 300 cadavers Favarger found fatty degeneration in 52 per cent., cloudy swelling in 41 per cent, and atrophy and heart weakness in 7 per cent. The heart was thus found affected in 300 out of 670 cadavers examined, exclusive of the cases of pronounced valvular defects. This remarkably large proportion of anatomic affections of the myocardium was a surprise to him. Comparing the anatomic findings with the clinical diagnosis, he found that the fatty degeneration had been diagnosed in only 14 per cent., the parenchymatous degeneration in only 7 per cent. and in all the other cases no traces of the heart affection had been detected during life or they had been interpreted erroneously. The diagnoses had been made by trained Viennese clinicians, and the conclusion is inevitable that in a large proportion of cases it is impossible to differentiate it. It is wiser to give up the attempt and to diagnose merely from the most prominent symptoms, the weakness of the heart muscle, myasthenia cordis. The cause of the myasthenia is either of an infectious or of a toxic nature, or due to anemia or to sclerosis. The clinical diagnosis of weakness of the heart muscle on the basis of the morbid process causing it, is sure to be correct, and it also directs attention to the necessity for strengthening the enfeebled heart musculature by rest and tonics.

56. **Pseudo-Appendicitis and Ileocecal Pain.**—Singer has had an extensive experience of cases of illness which simulated appendicitis but were in reality of other origin, and the appendix was found sound: In a certain number of cases, the operation for the supposed appendicitis banished all the symptoms although nothing was found in the appendix to explain them. In some instances it may be possible that slight malformation or displacement of the appendix or adjacent parts might entail disturbance in circulation, causing pain, but spontaneously righting themselves later or corrected by an operation. In other cases, fractional disturbances in the lower intestine simulated the picture of chronic appendicitis, but the spontaneous cure under change of air or hydrotherapy or other general measures cleared up the diagnosis. In other cases neuroses in the sexual sphere induced obstinate spastic contraction in the lower bowel with its train of symptoms, especially pain. When the latter is located in the ileocecal region the widespread dread of appendicitis at once locates the trouble at this point. In one of the cases he describes, McBurney's point was painful; the patient was a woman of 30, the rectum free. Examination revealed severe vaginismus, which was ascribed to masturbation. A course of cold hydrotherapy banished all the symptoms and there has been no sign of appendicitis since. Appendicitis may also be simulated by a kindly affection, as he has had occasion to observe in his practice several times. Intestinal parasites can also cause symptoms suggesting it.

58. **Radical Operation for Tuberculous Hip-Joint Disease.**—In the radical operation for a severe case of tuberculous coxitis Mosetig opens the field extensively by temporary resection of the greater trochanter, not disturbing the attachment of the transverse oblique abdominal muscles. After extirpation of the focus, he fills the resulting cavity with his iodoform filling, in which he implants the end of the femur. The legs are placed parallel and the abscess cavity is drained. The pseudoarthrosis which results is much better, he thinks, than ankylosis. His 4 patients thus treated are able to walk without trouble, merely requiring an insole 2.5 cm. thick. They can sit and stand without difficulty. In one case, a previous shortening of the limb of 3 cm. was half corrected by the operation. This method is applicable for the severer cases while that recommended by Lorenz, described recently in these columns, he thinks should be reserved for the milder cases. The Roentgen pictures show the extremely satisfactory anatomic result obtained.

69. **Roentgen Treatment of Leukemia.**—Rosenbach regards the sudden suppression of an essential symptom—such as occurs in leukemia when the white cells are reduced in numbers by Roentgen treatment—as a questionable advantage for the organism. The sudden and excessive demands made on it are a serious matter, the same as the rapid rise of the temperature after transient reduction by purely symptomatic treatment of the hyperthemia. He thinks that in leukemia a certain number of the white blood cells—and probably also of the red—are destroyed by Roentgen treatment. Others are attracted to the skin by the local irritation of the rays. These processes alter the composition of the blood to a certain extent, and as the blood is the organ which supplies stimuli for the functional activity of the tissues, the production of leucocytes is inhibited to a certain extent. It is an open question whether the radiation is itself the inhibiting factor or the direct or local action of the rays on the blood, or whether the products of the destruction of the blood cells may not be the determining factor. The inhibiting influence exerted by the rays is probably only a temporary compensation of the actual morbid cause, just as the benefit of purely symptomatic measures to reduce fever is experienced only so long as these measures are kept up. He warns against accepting these temporary effects as removal of the cause. The history of Roentgen treatment of leukemia is passing through the same phases as that of tuberculin treatment of tuberculosis. Instead of the maximal stimulus, the aim now is to use the smallest possible amount, and to treat patients with the smallest possible amount of stimulation.

71. **Local Massage for Hay Fever.**—Urbantschitsch gives an illustrated description of a little electric apparatus with which he massages the mucosa of nose and throat.

76. **Lymphogenic Retrograde Tuberculosis of Certain Abdominal Organs.**—Tendeloo relates a number of cases of tuberculosis of kidneys, suprarenals, sexual organs, liver, spleen and peritoneum in which the location and distribution of the foci conflicted with the assumption of a hematogenic origin. On the other hand, everything harmonized with the assumption of a retrograde lymphogenic origin. The absence of any other tuberculosis foci in the intra-abdominal organs and tissues, while such existed in the lungs or pleura, was another argument in favor of this assumption, as also the finding of dust pigment in the abdominal foci, suggesting that the tubercle bacilli had migrated from some intrathoracic focus by way of the lymphatics. The liver is connected directly with the thorax by the lymphatics, that is, there are no interposed glands, he has found, and he thinks it probable that a similar direct connection exists between the suprarenals or kidneys and the thoracic cavity.

89. **Experimental Immunization to Morphin.**—Argentina experimented on rabbits, finding that very slow, gradual administration of morphin induced more active immunization than when large doses were given in a comparatively short time. The aqueous extract of the brains of animals, in suitable doses, thus treated was able to neutralize the minimal fatal dose of morphin, but less actively than the serum of the animals. Large doses of the brain emulsion proved toxic.

90. **Parathyroid Treatment of Eclampsia and Epilepsy.**—Vassale's previous communications have been summarized in these columns. He relates here that no change was noted in one case of epilepsy under treatment with extract of the parathyroid glands from beef cattle, but in two other epileptics the improvement was most striking. One was a young woman who had had epilepsy from childhood and severe psychic disturbances. No other treatment had been applied for several years. He has noticed that dogs show marked changes in character after extirpation of their parathyroid glands, with hallucinations, depression with constant whining, resembling human melancholia, and states of excitement amounting to actual mania. Such symptoms as these are not observed in any other experimental intoxication. Removal of the thyroid gland does not induce these acute psychic disturbances, but merely a slow and progressive mental torpor as symptoms of myxedema develop. He suggests that parathyroid treatment should be given a trial in mental affections. The benefit that has been noted under thyroid treatment in certain cases of mental affections may possibly have been due to scraps of the parathyroid inadvertently used along with the thyroid, and the cases of failure to the absence of such fragments. He is convinced that the parathyroid theory of the origin of eclampsia harmonizes with the clinical facts observed. Latent functional insufficiency of the parathyroid gland with pregnancy or the puerperium superposed, causes the outbreak of eclampsia; the other causes that have been assumed to be the source of the trouble are merely co-operating factors. The latter may act by the cumulative action of their influences and those of the pregnancy of puerperium and together induce functional insufficiency of the parathyroids or cause definite injury to them. The trouble may likewise be due to congenital defects in one or more of the parathyroids. The last assumption would explain the occurrence of eclampsia in sisters and in cases of myxedema. Special attention should be paid to the parathyroid glands in postmortem examination of women who have succumbed to eclampsia.

91. **The Bacillary Formula in Tuberculosis.**—Mircoli emphasises anew that when bacilli lengthen out it is a sign of diminished virulence. He reviews recent works on the bacillary formula, all confirming his previous assertions on the subject. The streptococcal form of the tubercle bacilli in the sputa, especially if comparatively long, indicates a mild course of the disease, as it is a sign that the organism is opposing a vigorous resistance. Sclerosis will develop or is already developed. The short, thick forms of the bacillus have an opposite significance. Even a large number of the streptococcal shapes in the field is less unfavorable than the finding of even a few of the short, pulpy shapes. When these shapes alternate, the prognosis depends on which seems to be getting the upper hand.

93. **Excess of Blood Corpuscles in Tuberculosis.**—Mircoli thinks that far too little attention has been paid to the hyperglobulia of the tuberculous. It may be the explanation for the so-called "florid" cases of tuberculosis, and also the benefit of small repeated withdrawals of blood in incipient tuberculosis which Sydenham reported. A "florid" aspect with hyperglobulia should not be regarded as against the assumption of tuberculosis in dubious cases. He further calls attention to the fact that injections of tuberculin, previous to an operation, have the power to increase the leucocytosis, and thus enhance the resisting forces of the peritoneum. Isaeff reported several years ago that tuberculin is able to reinforce

the resisting powers of the peritoneum against infection. This is not surprising when we reflect that the active principle of tuberculin is its nucleinic or thymic acid, and that the latter is composed in large part of phosphorus. This explains why tuberculin itself, in certain individuals and circumstances, can exert a stimulating action in the general biologic constitution and on the blood-forming organs in particular. The nucleinic acid present in the tubercle bacillus is a hundred times more toxic than that of its congener, the thymic acid in the thymus. But the fundamental law holds good, and tuberculin, like nucleinic acid, like dead tubercle bacilli, like the semen, the thymus or spleen and like phosphorus, has a true stimulating action on the organism in a given dosage, under certain conditions, and hence on its general immunity and on the formation of blood. A suggestive fact was related not long ago by Arloing. He found that after animals had been inoculated in the spleen with tuberculosis, if splenectomy was performed not long thereafter, the animals died much more rapidly than the other animals with their spleens left in place, although studded thick with tuberculous lesions. The abundance of nucleinic acid in the spleen possibly conferred greater resisting powers on the organism. A tuberculous spleen is frequently associated with enormous excess of blood corpuscles, and this may possibly explain the "florid" cases of unmistakable tuberculosis occasionally observed.

96. **Importance of Helminths in Abdominal Surgery.**—Soma reports a case in which the healing of an abdominal wound was delayed by an ascaris which had worked its way into the wound. D'Alessandro has witnessed four similar cases, in one of which the emergence of the helminth through the wound infected it, with a fatal result. He advises that when the surgeon can palpate helminths through the walls of the intestines he had better remove them when operating for abdominal traumatism, even if it be necessary to make a small incision in the intestine for the purpose. Soma thinks that this would be comparatively useless, and suggests the injection of some worm-killing fluid into the intestine through the open wound. This would render torpid the helminths in the vicinity and further measures for their evacuation could be applied later.

98. **Certain Forms of Cirrhosis of the Liver and their Treatment.**—Schiassi does not accept the classification of liver cirrhosis advocated by Chauffard and others. He recognizes five varieties, based on the anatomic findings, the venous, the arteriovenous, the biliary, the capsular and the mixed. The ascites may be due exclusively to obstruction in the portal circulation or exclusively to the peritonitis, or to both combined. When due exclusively to the portal obstruction, an early operation has every prospect of success. Numerous clinical and experimental data have established the fact that the portal circulation can be effectively restored by anastomosis even when obstruction is complete. When a patient with cirrhosis of the liver and ascites suffers from vague pains in the abdomen, with rise of temperature, right pleural effusion and sensitive liver, and when the ascitic fluid contains a large proportion of albuminoids and has the characters of an exudate, then the indications for surgical intervention should be formulated with extreme care. Tuberculous peritonitis accompanying cirrhosis of the liver may be cured by a laparotomy as also peritonitis from other causes. Parona has reported a case in which he opened the abdomen intending to suture the omentum in a Talma operation. The omentum was missing, and he therefore merely sutured the abdomen after evacuating the fluid. The patient recovered. Similar cases have been reported by others since, and the conclusion seems inevitable that the effusion in these cases is merely the expression of a readily curable inflammation. He adds that the inflammation is curable only when it is a comparatively mild, chronic inflammation. If the inflammation is not in this chronic phase, the operation might easily aggravate it. He is convinced that some of the deaths that have been known to occur soon after laparotomy for peritonitis were due to aggravation of the existing peritonitis. The surgeon should be guided by the rule that laparotomy is indicated at once on the diagnosis of ascites due exclusively to portal obstruction. The omentum should be transplanted and other measures taken according to individual indications. On the other hand, if the ascites be due, either wholly or in part, to inflammation of the peritoneal serosa it is unwise to attempt any surgical interference until the inflammation has passed into the chronic stage. If necessary, the patient can be tapped. The laparotomy should be postponed until four months at least after the appearance of the ascites. During the interval medical measures should be used, milk diet, calomel, possibly iodin subcutaneously, and liver extract or fresh livers might be given to advantage. He has only good results from this organotherapy.

99. **Is there Danger in Leaving Part of the Cervix.**—Gasparini tabulates the details of 51 cases since 1898, in which incomplete hysterectomy was done for various reasons. There were 3 deaths. The mortality after complete hysterectomy is higher than this, as he shows by comparative tables. He adds that no case of carcinomatous or sarcomatous degeneration of the stump occurred in his series.

101. **Differentiation of Typhoid Bacillus.**—Trapani asserted *that the typhoid bacillus behaves differently from the pseudotyphoid and the colon bacillus in the presence of glycerin.* He transfers a platinum loop of the culture to 1 c.c. of distilled water, and keeps the test tube in the thermostat for an hour at 30 C. Ten loops of the contents are then transferred to another test tube containing .5 c.c. of neutral, sterile glycerin. A fresh loop is taken each time to prevent mixture of the fluid with glycerin. The glycerin tubes are left undisturbed in the dark at room temperature for forty-eight hours. Agar plates are then inoculated with the glycerin bacilli. The pseudo-typhoid and colon bacilli proliferate undisturbed while the typhoid bacilli are unable to proliferate after their sojourn in the glycerin.

103. **Intravenous Injections of Corrosive Sublimate in Scarlet Fever.**—D'Andrea relates that there were no deaths in 52 cases of scarlet fever during a recent epidemic, but that the disease then assumed a more malignant form and 6 died out of the next series of 12. Alarmed by this mortality, he treated the next 4 patients by intravenous or subcutaneous *injection of from 2 to 4 mg. of bichlorid of mercury.* All were very severe cases, but recovery ensued in all. The improvement was so marked under this treatment that he has since treated 9 cases of severe typhoid and one of puerperal infection in the same way. He calls attention to the pronounced antithermic action of the bichlorid of mercury when used intravenously or subcutaneously. The temperature drops in from two to six hours.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, dictated by their merits, or in the interests of our readers.

SCIENTIFIC REPORTS ON THE INVESTIGATIONS OF THE IMPERIAL CANCER RESEARCH FUND. Under the direction of Royal College of Physicians of London and Royal College of Surgeons of England. E. F. Bashford, M.D. Part I. The Statistical Investigation of Cancer. Part II. The Growth of Cancer Under Natural and Experimental Conditions. Paper. Pp. 58 and 96. Price 2s. 6d. each part. London: Taylor & France, 1905.

FIRST AID IN ILLNESS AND INJURY. Comprised in a Series of Chapters on the Human Machine, Its Structure, Its Implements of Repair and the Accidents and Emergencies to which It is Liable. J. E. Pilcher, M.D., L.H.D., Ninth Edition; 208 illustrations. Leather. Pp. 356. Price, $2.00. New York: Charles Scribner's Sons. 1905.

EVOLUTION OF MAN. A Popular Scientific Study. E. Haeckel. Vol. I. I [illegible] Ontogeny. Vol. II. Human Stem-History [illegible] from the Fifth (enlarged) edition by [illegible] Total pages 905. Price $10.00. New York: G. P. Putnam's Sons, 1905.

TEXT-BOOK OF PHYSIOLOGY, Normal and Pathological, for Students and Practitioners of Medicine. W. S. Hall, Ph.D. Second edition, Revised and enlarged; 340 engravings and Three Colored Plates. Cloth. Pp. 795. Price, $4.00 net. Philadelphia: Lea Brothers & Co. 1905.

Addresses

STATUS OF MEDICAL AFFAIRS IN THE PHILIPPINE ISLANDS.*

JOHN R. McDILL, M.D.
MANILA, P. I.

The account of the first public and scientific meeting of the Philippine Islands Medical Association was read no doubt with considerable interest and some curiosity by many of the 40,000 readers of The Journal of the American Medical Association, with which Association we are affiliated. We introduce ourselves to them and to this community by rendering an account of our environment, who we are, of what has been done in medical channels, and also something of what we hope to accomplish.

History tells why we came to the Philippines, but the good friends at home who have never been here, do not understand why some of us remain.

The American medical men who first came to this archipelago and who laid the foundation of modern research medicine, wore the uniform of the United States army and volunteer surgeon. It is doubtful if one of us thought that here he might make a new home and find new fields of labor. For two years our life was that of the soldier, and medical affairs were the many and arduous duties of the army surgeon in field and garrison. At the end of active military service, those of us who knew anything at all of the art of living to begin with, learned to adapt ourselves to the new physical conditions and the exotic climate and were more than ever constantly impressed with the beauty and resources of the country. We have come to esteem to the utmost the climate which so effectually guards many of you against the too strenuous life and which is almost ideal eight months in the year, even in Manila. Our professional experience has proven that, excepting some intestinal disorders which we are rapidly preventing and curing and a limited amount of epidemic infectious diseases, there is nothing unusual about the kind or amount of disease encountered here, or its successful treatment when hospital care is available. The surgeons' work has fully demonstrated that ideal wound healing and convalescence after operation is as much the rule here as anywhere in the world. We physicians also know and appreciate that the dread diseases of childhood so prevalent at home are rare here and that of all the ills, particularly among women, from real bodily ailments to a poor complexion, for which the climate is invariably blamed, the great majority are hereditary or acquired. were brought here by the patient and often aggravated by careless and unhygienic living. For old people and children the climate is an earthly Elysium.

The complement to the climate is the beauty and charm of the mountainous nature of the islands which invite excursions where, among thrilling scenery and invigorating cold, one finds a hunter's paradise in woods full of deer and wild boar and in marshes teeming with feathered game, which have scarcely ever heard a gun. Those who need or prefer to take vacations abroad can have pleasant voyages among our southern islands or to the nearby and interesting countries of China and Japan, Java and the Straits Settlements, or further to India.

The greatest general interest at present is in the result of the Benguet experiment to alleviate the life of foreign residents. One hundred and thirty miles from Manila is a government reservation in the Benguet Hills, 6,000 feet above sea level, where there is an actual temperate climate and where amid inspiring views one inhales cool, invigorating and exhilarating mountain air, flavored with the breath of Norway pines, where trips on foot or horse can be enjoyed for miles on the plateaus and hills, where in the evening fires are necessary in the houses and three or four blankets essential for a comfortable night. This region is now open to the public by the completion of a colossal piece of road building and can be reached from Manila, when rails are laid, in a few hours. The successful completion of this much discussed and much abused road for the opening up of a summer residence in these hills will have more to do than anything else with solving the problem of how we and our families can exist, perhaps permanently in this tropical climate, outside of our proper racial zone and the peculiar environments, thought to be essential to our well-being and to our proper term of life.

With the improved and constantly improving conditions of living, we believe that almost all will agree that by observing the normal and moral life, healthy Americans can live about as long here and enjoy as good health and do as much good and hard work more than three-fourths of the year as we could in the homeland. And that is enough for anyone. Yet our friends at home persistently pity and commiserate us and wonder what keeps us here, but from now on, at least when we strike our balance between what we had in our former prospects and what we now have and expect in the glowing future, it is surely, remembering the fewness of our working years, a perfectly natural spirit that detains us here to work on in the hope of tilling to the utmost the unscratched fields of this virgin country that beckons the followers of almost every occupation and every profession. In our world of embarrassments we have always the restful feeling that we can rely absolutely on the friendship, power and activity of our home government.

---

* President's address, delivered at the second annual session of the Philippine Islands Medical Association, Manila, P. I., March 1, 1905.

SOME INSULAR MEDICAL INSTITUTIONS.

Pride in the achievements of the Insular Board of Health, especially in its last three years' work under inconceivable difficulties, is shared by the medical profession and public alike. So valuable are the healthful conditions its intelligent and scientific labors have helped to create, that other government and commercial measures, no matter how vital or how earnestly attempted, could not have been so fully and successfully carried out. Manila is now a healthful and safe city and when in the near future the extensive public improvements now under way are completed, it will be not only the healthiest and handsomest, but the most prosperous city in the Orient.

Following the establishment of the Board of Health came the Government Laboratories and its scientific libraries, much criticised because of their supposed cost when other institutions were regarded by the public as entitled to precedence. From a scientific standpoint, however, they place the islands second only to Europe, America and Japan, and their economic value has already been inestimable through their work in combating disease in man and animals, in demonstrating the resources of the country and in saving crops from the ravages of pests.

These laboratory facilities, it should be remembered, are freely open to research workers from any part of the world; original investigations of far-reaching importance have already been given to mankind and original research work is constantly going on.

With the coming from the public schools of native candidates for general science and medical courses, these laboratories, with slight alterations, will provide at once the facilities for and teachers of the fundamental branches, or first two years of such courses which are now taught entirely by laboratory methods.

HOSPITALS.

An infectious disease hospital of permanent construction for 100 beds was opened in January, 1904. Temporary arrangements for the care of (75 male and 15 female) insane have just been completed. A venereal detention hospital has been in operation under government care for four years and there is a special hospital for civil employés. The Women's Hospital, founded by Mrs. Whitelaw Reid, after an existence of nearly two years, succumbed in 1902 to opposition, hard times and mismanagement. A leper colony has recently been established on one of the smaller islands, but a general hospital in which the medical profession and the laboratory scientists, with their unlimited facilities, could properly treat and investigate disease among the natives has not yet been established even on a temporary basis.

This country is overrun with untreated chronic diseases and would furnish enormous material for investigation. Full three precious years have been wasted in which work of greatest importance could have been accomplished. Board of Health statistics show that the mortality of infants in the first year is 60 per cent., and that even in Manila 52 per cent. of all deaths occur without medical attendance. Think of what could have been done by the study of 100 cases of infantile disease and 100 cases of dysentery and beriberi with any sort of hospital accommodations by our trained clinicians and investigators long here and yearning for the opportunity.

When a government general hospital does come, may the grave question of management be rightly decided, and may the management remember that in the treatment of disease the evils of ignorance and faith cure cults can be best combated only when medical science is put into close relationship with the highest moral and religious influences.

MEDICAL ORGANIZATIONS IN THE PHILIPPINES.

The history of medical organization since American occupation is brief. During the military times an army medical corps lyceum was established by Colonel Greenleaf and flourished for a few months. In 1901 a general medical organization for the islands was under way, but was discouraged by a request from the Civil Commission that for political reasons the project be abandoned, and it accordingly was.

July 4, 1902, a call to form the Manila Medical Society was signed by ten American and English physicians; organization was effected at once on the basis laid down for local societies by the American Medical Association. The purposes of the society, as stated in the preamble, are "to promote the science and art of medicine, the cultivation of fellowship, exchange of experience, the maintenance of ethical standards, and the promotion in general of the interests of the profession and the welfare of the public."

Monthly meetings are held and the character of the papers, many original, and the attendance and interest shown in the discussions give it a scientific importance that compares favorably with some of the best medical societies at home. It has been a great encouragement and benefit to its members.

At the annual session of the American Medical Association in New Orleans in 1903, a body of over 15,000 physicians, representing several hundred subsidiary societies, the affiliation of the Manila Medical Society was authorized on the basis of a state organization. This was effected in September, 1903, by organizing this association, the Manila Medical Society becoming its first component society, which preserves the integrity of future local or provincial societies. Thus the Manila and any future societies become, through this Philippine Islands Medical Association, the only avenue in this part of the world to membership in the great home body.

The councils of the local and provincial societies, like the houses of delegates of the state and national organizations, are representative bodies of picked men, which deliberate on and carefully dispose of many of the practical medico-social, medicolegal, medico-political and medico-material problems constantly puzzling us as a well-developed unit in the social order of the age. (Simmons.)

THE FILIPINO MEDICAL MAN AND HIS SCHOOLS.

Of greatest interest to us when we found time to make their acquaintance were our Filipino colleagues. We found them courteous and charming in manner, alert and devoted to the interests of their patients, apparently enthusiastic in medical affairs, good students of French and Spanish literature, and liberal purchasers of new instruments and remedies. They have two striking characteristics, an astonishing capacity to absorb and expound theory, and they have occupied an unique social position in that the abler members of the profession have always been foremost among the political leaders of their country.

An interesting feature of medical practice here was the custom, still somewhat in vogue, of charging enormous fees for even ordinary services, sometimes running up into the tens of thousands, and the fact that these delightful fees were often collected was probably due somewhat to the political importance of the profession. Their general education was in the schools of the religious orders, their professional training in the medical department of the University of Santo Tomás and in some instances supplemented by a course of study in Spain or France. Attracted by the personality of the better class of native doctors, earnest overtures have been made to fraternize and interest them in medical society work and making all due allowances for difference in language, customs and education, we are not able to satisfactorily explain the reason of our almost total failure to affiliate them. We are glad to say that a year ago a native and Spanish medico-pharmaceutical society was established and the American Principles of Medical Ethics adopted. We are about resigned to the belief that no close community of professional interests will be possible until the arrival of a new generation of native doctors educated in English and in the modern university schools, where they are actually educated instead of having some information imparted to them.

The existing Spanish institutions that interest us are three, the University of Santo Tomás, its Medical College of San José and the Hospital of San Juan de Dios.

The college of Santo Tomás was founded for the Filipino people in 1612 by the Dominican, Miguel de Benavides, the third archbishop of Manila. It was raised to the status of a university in 1645. From 1785 it has been styled the Royal and Pontifical University of Manila and is the only university authorized to issue diplomas in theology, law, medicine and pharmacy.

Graduates of the several church colleges, whose average age is about sixteen years, are admitted without examination. It has had 118,741 students, less than 3 per cent. of whom, or 3,434, have graduated. It has at at the present time 982 students in all departments.

By royal decree of 1876, reorganizing this university, the departments of medicine and pharmacy were created, with a provision that they be installed in the famous college of San José, which was lost to the Jesuit fathers by their expulsion in 1768. Medical instruction had begun, however, in 1871.

The affiliation of the Medical School of San José with the University of Santo Tomás, which issues the degrees, seems rather nominal as the school is quite autonomous, resembling in this respect the relation of many of our home proprietary medical schools to some universities.

The published list of the medical faculty shows 81 names, and of these about 20 are the active professors and teachers. To date, after 35 years of existence, diplomas have been granted to 10 doctors and to 247 licentiates of medicine. The difference between doctors and licentiates is an extra college year and 100 pésos ($50) more fees. The average age of graduates is 26 years. There is another class, called cirujanos ministrantes, who, after two years' instruction in college and hospital, are licensed to practice medicine only and where no doctor or licentiate is available.

The medical course lasts seven years; the fees for the entire course was 242 pésos ($121). The licentiate pays about 200 pésos for his title, and the doctorate degree costs 350 pésos and one more year's study. The present class numbers 135. The graduating class for 1905 consists of but 5 members.

The teaching, which is didactic and clinical and not graded, is mostly given in the Hospital of San Juan de Dios, founded in 1596 and conducted by the Sisters of St. Vincent of Paul. The hospital has now 27 Sisters, about 200 patients, 8 attending physicians, and 14 of the professors of the Medical College of San José give clinical instruction to medical students.

STATUS OF MEDICAL CONDITIONS AND NEED OF MEDICAL SCHOOLS.

To supply the medical and sanitary needs of this country, 2,000 or 3,000 native physicians and sanitarians should be educated here during the next 20 years.

The population of the islands is about 7,500,000 people, 6,000,000 of whom are said to be Christians. The statistics of the Manila Medical Society show that the total number of licensed physicians is only 360, and 217 of these are in the city of Manila. These figures mean that, although in Manila there is one physician to 1,013 inhabitants, in the provinces the proportion is but one to 51,786, or one physician to each 430 square miles.

In the policy of the government for the general improvement of the Filipinos, perhaps the greatest results are looked for from the Department of Education. With the coming of advanced students in June of next year and the necessity of professional schools for them, it is essential that these schools be established along the lines of the best modern thought, the university plan.

The present status of medical science as defined by Dr. Billings requires and demands a university medical college course. By a university medical college is meant a medical school which is directly connected with and a part of a university, the university fixing the requirements and controlling the admission of students to the medical department. For this ideal and practical scheme of medical education, all the fundamental sciences must be taught entirely by the laboratory method of individual instruction and by teachers who give their whole time to research work in connection with the instruction of students. This plan could be carried out now in the government laboratories, which have the men and facilities to instruct in anatomy, physiology, chemistry, pathology, bacteriology, etc.

The second two years of senior college work should be supplied with facilities of equal rank in clinical medicine, surgery and obstetrics by the endowment of research hospitals in which the instructors devote their entire time and energy to teaching and investigating disease. The cost of these hospitals, if ideally built, equipped and endowed in perpetuity, is stupendous, and in the United States two millions is thought to be about right for each of these hospitals.

No teaching hospitals, however costly, would serve their purpose without an abundance of cases to choose from, but the clinical material available here is practically unlimited. The government has set aside a centrally located site of 23 acres in the city of Manila, ostensibly for hospital purposes, and these two things alone should attract the attention of some man of large means looking for the right opportunity to benefit mankind and assist the Filipino people at the same time.

Untrammeled by traditions of a past or by proprietary medical schools and urged on by the necessity of supplying the country with sanitarians and physicians as fast as possible, a demand that can not be supplied in many years, there is here an unique opportunity for the establishment of the ideal university and affiliated professional schools. There will be no lack of candidates; the Filipinos are bright, earnest, capable students and especially inclined to the study of the learned professions.

This association is, of course, particularly interested in the medical department of a Philippine university, and we find our encouragement in the peculiar preference of the native for our profession; in his alert and inventive mind, coupled with a natural dignity of manner and a certain manual dexterity and accuracy and in the fact that the 140 students in the United States are showing marked aptitude and progress in their studies.

In conformity with the highest purposes of all medical organization, which are the extension of medical knowledge, the advancement of medical science, the elevation of the standard of medical education and the enactment and enforcement of just medical laws, this association, through its permanent Committee on Public Policy and Legislation, petitioned the governor-general in January of this year to appoint, without delay, a board of regents, provisional or otherwise, to report on a plan for the formation of professional schools as part of a university system. This action was taken after consultation with the superintendent of public education, who had already recommended steps looking to the establishment of a university, and who stated to us that by June, 1906, there will be between four and five hundred students who can take some of the branches of a preparatory university course.

It is also confidently believed by the normal school teachers that their schools will be on the plane of the American high school in another two years.

Our greatest hope for the future lies in the education of the people in sanitary matters and the enforcement of laws, and this can only be accomplished by a small army of native sanitarians. Preventive medicine has profited far more than curative medicine by the discoveries of recent years, hence a Philippine medical school should devote its first years to supplying this most pressing need by turning out as many sanitarians as possible. While always standing for the highest practicable requirements, in view of our distressing lack of this class of men, the requirements for admission and graduation should be minimized at the start; to balance this compromise, the first classes graduated can take postgraduate work later in their careers.

Billings estimates the cost of a complete modern medical education to be between $6,000 and $8,000. Keen has shown that the teaching force has increased 110 per cent., against an increase of fees paid by students of less than 100 per cent. It is clear that state aid or private endowment must be had.

Quoting from Dr. Dodson's address, we hear again that at present private beneficence holds out much the larger promise, and in the hope of such assistance there is every reason to feel the greatest encouragement. The recent gifts to medical institutions and for the promotion of research on a princely scale are conclusive evidence that men of affairs and of large capital, whose chief desire is to find a use for their money which shall be of the greatest service to mankind, have come to realize that in these medical channels, especially, large gifts are more likely to yield a certain speedy and bountiful return in good to the world. Since 1900 nearly 300 millions represent the amount of gifts and bequests for all purposes in the United States alone.

One year ago to-day Dr. W. W. Keen[1] made a ringing plea for increased endowments for medical instruction which will soon vitally concern us in what he supposes some would call "far-off, barbarous Manila." The main reason he advanced for generous endowments from the public is the sordid commercial value of the profession to the public. Dr. Keen was not talking of the value of health to anybody or of the desire for the health of those dear to us at home, nor of the kind father that may be lost to a young and dependent family, of the loving mother or of the dear child whose place can never be filled in our hearts or homes, but merely of the profession's value to the community in hard cash, dollars and cents.

The horrors of quarantine of a few years ago, he points out, have been almost abolished by reason of the research work of the medical profession. We no longer fear cholera, the plague, yellow fever or even typhoid fever, because we have killed the rat, we can quarantine or destroy the mosquito, we have barred out the fly and we are boiling and filtering our drinking water. All these things have been shown to be needful and efficient for the prevention of disease by the most patient scientific laboratory work.

A few years ago a single case of cholera or yellow fever in any great port would have meant the loss of millions of dollars to the merchants, but to-day these cases, even of plague, scarcely create a ripple of excitement, because the community knows that our able medical men have these diseases by the throat. Look at the epoch-making work of Dr. Walter Reed and his fellow-workers in Cuba. For the first time in 170 years Cuba has been made free and kept free from yellow fever, and the merchants from New Orleans to New York are reaping the benefit of this unselfish labor in hard dollars on the credit side of their accounts.

The horrible character of plague we scarcely appreciate. In the fourteenth century, twenty-five millions of human beings lost their lives in Europe alone, and even to-day in India, among the ignorant people, over two hundred thousand lives are lost every year from plague. Haffkine's inoculations have diminished the susceptibility of the people by 75 per cent., and the mortality in equal proportions, and the time is coming when the plague, like yellow fever and smallpox, will be practically wiped out.

Again, we must not forget what smallpox was in the past. In the eighteenth century sixty millions died from smallpox in Europe alone, and almost all the living were left with the marks of the disease on their persons. It was as uncommon in the streets of London to see a person not pockmarked, before that memorable day when Jenner inoculated young Phipps in 1796, as it is to-day to see one in New York who is pockmarked. Consider what these millions of saved lives mean in revenue to the state, to the family, in the prevention of pauperism, and the comfort of human beings; then, we must appreciate the value of the services of one man, the most magnificent benefactor of the human race that ever lived, Edward Jenner.

In 1890, Keen estimates that there were 157,000 unnecessary deaths in our large cities. The sanitary reform in 1895 saved in three years a total of 21,300 cases. As there is an average of twenty-eight cases of sickness for every death, sanitary reform in those three years prevented about 600,000 cases of sickness. And who were the reformers? The physicians. The hundreds of millions to be saved in fifty years in one large city alone would enrich the most avaricious of nations.

You all know what has been done in diphtheria in our day, and *it has not been done* by constant and fruitless trials of various supposed means of cure, but it has been done by exact laboratory work by quiet men working far away from the sick room, with not a single human patient under their care, men who are not practitioners of medicine, but pathologists and bacteriologists, experimenting on rabbits, guinea-pigs and mice instead of on men, women and, especially, dear little children, and thus working unobserved and unheralded and unseen they have given to the human race a boon second almost to that of Jenner. The mortality of diphtheria has fallen from 40 to 8.8 per cent., and in laryngeal cases before the serum treatment the mortality was 73 per cent., recoveries 27 per cent., and now precisely the reverse has become the case.

---

[1] Address at the dinner to Dr. D. B. St. John Roosa, March 1, 1904, by Dr. W. W. Keen of Philadelphia. While elaborating a similar arrangement the reprint of this stirring address providentially arrived the day before our meeting, and was in part appropriated bodily. It could not be better expressed.

Great epidemics of typhoid have been traced to one case contaminating the water supply of a city, which is preventable.

Malaria was formerly thought to come from marshes and decomposing vegetable matter; now, thanks to the investigations of medical men, you all know perfectly well that if you shut out the mosquito you shut out malaria, as well as yellow fever. When the United States digs the Panama canal, there will be seen a splendid object lesson in sanitation that will carry conviction to all of the money value of medical research in the saving of millions of dollars and thousands of lives.

We are on the verge of an equally beneficent improvement in the treatment of tuberculosis. In Germany the cure of even 10 per cent. adds two millions annually to the resources of the state, and human lives and human happiness can not be reckoned in dollars and cents.

In military hygiene and sanitation the money return is equally profitable. Witness the fearful losses of the British from preventable disease in South Africa, or, worse still, our own losses in the Spanish-American war, where the mortality from wounds was 1 per cent. and that from preventable disease 70 per cent. This could be now characterized as governmental murder through criminal neglect, since the Japanese have practically eliminated disease as a factor in war.

The Japanese determined that their only hope in the war with Russia was that every man who died should die on the field of battle, and in that way neutralize the superiority of two million Russians under insanitary conditions with half a million Japanese protected from disease by a capable medical corps backed up by their government with every authority and facility to prevent disease.

Translate all these facts into figures and the commercial value of modern surgery and of all the medical work done in diseases of animals, and who can tell us the money value of medical research work?

Dr. Pritchett, in McClure's magazine, well says that "The research habit, once thought so far removed from utilitarian ends, is to-day the greatest financial asset of Germany," and we Americans, whether at home or in her possessions, can acquire that "research habit" and teach it to our charges and make it our best and most valuable financial asset, but this takes money.

On account of the complexity and multitude of questions to be solved, such a board as suggested would hardly have a complete outline of plans in two years, and a further reason for its prompt creation lies in the fact that some such definite action is necessary in order to successfully invite private endowment, which must be secured in view of the enormous expense entailed by modern university school methods, particularly in the medical department; further, the appointment of regents would give the department of education the exact impetus it needs at the present time by opening up to its students the vista of higher education.

There is surely a rich man, or better still a rich woman, somewhere who can be found willing to contribute by his or her means to establish a Philippine University Medical School and perhaps temporarily to assist the present school of San José to increased production until it can be absorbed by the university.

The medical profession is but waiting to assist with all its power an earnest and active board to point out to donors the genuine and lasting pleasure that it gives to share in the great and lasting benefits given to humanity by the research workers in medical fields.

THE TEACHING OF PEDIATRICS.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON DISEASES OF CHILDREN, AT THE FIFTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, PORTLAND, ORE., JULY 11-14, 1905.

JOHN LOVETT MORSE, A.M., M.D.,
Instructor in Pediatrics, Harvard Medical School; Assistant Physician at the Children's Hospital and at the Infants' Hospital; Visiting Physician at the Floating Hospital.
BOSTON.

Harvard requires for admission to its medical school a degree in arts, literature, philosophy or science from a recognized college or scientific school, except that those who have acquired an equivalent education may be admitted by a special vote of the administrative board in each case. All candidates are required to satisfy the faculty that they have had a sufficient course in theoretical and descriptive (inorganic) chemistry and qualitative analysis or to pass an examination in the same.

The course of study required for the degree of M.D. is of four years' duration. The first three years are devoted to prescribed work and the fourth year entirely to elective courses. A minimum of 1,000 hours' work is required of each fourth-year student. Written examinations are given in the studies of the first three years. In the fourth year the nature of the examination is determined by each department, subject to the approval of the faculty. The whole of the first half of the first year is devoted to anatomy and histology; the whole of the second half to physiology and physiologic and pathologic chemistry. The first half of the second year is given to pathology and bacteriology. The second half of the second year is devoted to elementary medicine and surgery, with lectures on hygiene and pharmacology, and is preliminary to and preparatory for the third year. Two hours a day of this half year are devoted to section work, in which the students are given instruction in physical diagnosis, examination of the blood, urine, gastric contents and so on, in small sections in the hospital clinics.

The third year is devoted largely to medicine and surgery. Pediatrics, neurology, dermatology, obstetrics, gynecology, orthopedics, syphilis, psychiatry, therapeutics, laryngology and otology are also taught more or less in detail. The first two hours of each morning are devoted to clinics and clinical lectures for the whole class, and the second two hours to section teaching. Lectures to the whole class occupy two or three hours of every afternoon.

The present third class consists of about seventy men and is divided into thirty sections of two or three men each. These sections are assigned to work in groups varying from two to ten. This work consists of bedside instruction in the wards or out-patient departments of the various hospitals. Enough instructors are provided so that, if every student is present, no instructor has more than six students; usually he has but three or four. The students in this way receive almost individual instruction. Each exercise lasts from one and one-half to two hours. The exercises are so arranged that, as a rule, every section is busy somewhere. The following extracts from the tabular views of the two terms show much better than any description the arrangement of the section teaching.

The fourth year, beginning with this autumn, is elective. The subjects are divided into courses. Each course equals 125 hours. The student must take 1,000 hours, or eight courses. This is equivalent to one course a month for eight months. Courses are given all day for one month, or half a day for two months. All day means from 9 to 1 and from 2 to 6 every day. Half a day means from 9 to 1 or from 2 to 6 every day. The student must decide on his courses for the year at the beginning of the year. The students are divided among the different months by a special committee of the faculty. Each department decides what the work is to be in its courses. A man may take more than one course in a given subject if he desires, but can not devote the whole year to one subject without the consent of the head of the department. The courses are not graded.

The courses advised by the committee for men who intend to enter general practice include: Medicine, 3 courses; obstetrics, 1 course; surgery, 1 course; pediatrics, 1 course; neurology, dermatology or gynecology, 1 course; otology, hygiene, bacteriology, histology, physiology, chemistry or neuropathology, 1 course.

The elective fourth year enables the student to take a general course of study or to devote a part or all of his time to the subject or subjects in which he is most interested. The future alone can tell how it will work out. In all probability most of the students will select their courses with a view to entering general practice, while only a few will turn at once to the study of a specialty. The personal popularity of the instructors can not fail, however, to influence the students to a certain extent in their choice of courses. On the whole, I think that men who have studied hard for three years after having been through college can be trusted to choose wisely and to make the best of their opportunities.

The department of pediatrics consists of a professor, an assistant professor of contagious diseases, an instructor, a clinical instructor and two assistants. The department practically controls the medical wards of the Children's and the Infants' hospitals, as the nomination of the visiting physicians to these hospitals is in the hands of Harvard University. The visiting physician nominates his subordinates. These hospitals afford a large amount of clinical material for instruction both in the wards and in the out-patient departments. About 700 medical cases are treated annually in the wards of the Children's Hospital and about 200 cases at the Infants' Hospital, while about 3,000 medical cases, making 6,000 visits, come to the out-patient department of the Children's Hospital and about 2,000 cases, making 7,000 visits, to that of the Infants' Hospital. The surgical sides of these hospitals can also be utilized, if desired. The Infants' Hospital wards are limited to babies under 2 years, and the great majority of the out-patient cases are infants, although children as old as 12 years are treated. Both infants and children are treated in both the wards and out-patient department of the Children's Hospital, but the vast majority, especially of the ward cases, are over 2. The present assistant professor of contagious diseases is resident physician at the contagious department of the Boston City Hospital. About 2,000 cases are treated there annually, mostly of diphtheria and scarlet fever, but some of measles and chicken-pox. Smallpox patients are not admitted.

Instruction in pediatrics in the third year is given to the whole class by lectures, clinical lectures, recitations and case teaching, and to sections in the wards. Thirty lectures, 24 clinical lectures, 10 recitations and 10 exercises in case teaching are given. The first lectures are on diphtheria and the exanthemata, preparatory to the section teaching at the hospital for contagious diseases. The theory of infant feeding is then taken up and is followed by 5 practical illustrated lectures on the preparation of modified milk in all its forms. The next lectures are devoted to the diseases of the gastrointestinal tract, and are immediately followed by a series of clinical lectures on these diseases. The topics of the rest of the lectures vary from year to year, but the diseases of nutrition and those of the heart and lungs are almost always taken up. The lectures continue until the first of May. The clinical lectures start at the beginning of the year and continue until April. The recitations begin in February and are designed to cover the more important of the subjects not touched on in the lectures. The case teaching closes the year. In this form of teaching each student is given a typewritten copy of the history and physical examination of an actual case. He is supposed to study this case carefully with his text-books before the exercise, when it is taken up and discussed in detail. The exercise is conducted chiefly by questions, the object being to make the students think for themselves as far as possible. Particular attention is devoted to the details of treatment.

Each section has seven or eight visits at the hospital for contagious diseases and from 20 to 22 at the Children's and Infants' hospitals. At the hospital for contagious diseases the students have the opportunity to become intimately acquainted with the exanthemata and diphtheria. Intubation is at present taught entirely on the cadaver, but it is hoped that in the new elective fourth year it will be possible to teach it on the living as well. At the other hospitals the students see a considerable number and variety of cases. In this section work the time is devoted to the examination and discussion of the cases by the students themselves under the supervision of the instructors, as little time as possible being given to didactic teaching.

In the new elective fourth year the department of pediatrics offers a course each month. A course occupies the whole of each day during the month and counts for 125 hours. A student may take more than one course in pediatrics, if he desires, but can not devote the whole year to it without the consent of the professor of pediatrics. The courses are not graded. The students electing pediatrics are divided among the months by a special committee. The department of pediatrics decides what the work shall be in each course.

The character of the teaching has not yet been entirely decided and must, of course, depend a good deal on the number of students electing the subject and the number to be taught in each month. The general plan, however, is to have the students assist in the work of the hospitals, both in the out-patient departments and in the wards, and to study special cases or groups of cases under the supervision and with the assistance of the instructors in the department. They will be required to do considerable reading in connection with their cases and, if possible, to undertake more or less original investigation. Those who elect but one course can not, of course, go very far in the subject, but those who elect several courses or who devote the whole year to pediatrics will have the opportunity not only of getting a good comprehensive grasp of it, but also of following up special lines of work and of carrying out original researches.

Special courses for graduates have been given in the past throughout the winter months. In the future graduates will be admitted to the fourth year elective courses and the character of this instruction modified as far as possible to suit their individual needs. Summer courses, open to both graduates and undergraduates, are given in each of the summer months. In August and September they are arranged to occupy the whole of every morning. The opportunities for graduate instruction in pediatrics in Boston have not been generally known or appreciated as they should have been in the past. It is hoped that more advantage will be taken of them in the future.

A dash between numbers on both tables includes the corresponding sections.

I have described the teaching of pediatrics at the Harvard Medical School in so much detail for several reasons, one of which is that as I am more familiar with it than with that in other schools I can take advantage of both its merits and defects in discussing the best methods of teaching pediatrics in our schools. Another reason is that, owing to the untiring energy and incessant effort of Dr. T. M. Rotch, the present professor of pediatrics, the department of pediatrics at Harvard has for many years been accorded more nearly the consideration which the importance of the subject deserves than has been granted in other schools. On this account the department has had the opportunity to work out many problems in methods of teaching and by actual experience to arrive at a comparatively high grade of efficiency. The department of pediatrics at Harvard is a department by itself and not a part of or subordinate to any other department. Pediatrics can never be satisfactorily taught unless it is a separate department. If it is made a part of the department of obstetrics or of gynecology, as in some schools, it is certain to be neglected and to be improperly taught. It is too important a subject even to form a part of the department of internal medicine. When it is in that department, as it is in some schools which in other ways are most progressive, it is sure to be insufficiently and imperfectly taught, as it is in them. No man is competent to appreciate how much there is to be known about pediatrics and how little there is known about it, even by the best men in other lines, except the man who makes it a specialty. If the faculties of our medical schools did appreciate these facts there would be an independent department of pediatrics in every medical school. No one who does not make a specialty of pediatrics is, moreover, competent to teach it as it should be taught.

While the time allotted to pediatrics in the third year at Harvard is, of course, entirely inadequate in which to teach the students all that they ought to know about the subject, it is, I think, about all that its relative importance justifies. Pediatrics is recommended, moreover, as one of the fourth year electives for those students who intend to go into general practice and opportunity for further study is also provided in the fourth year. This division of the work between the third and fourth year is, I think, fairly satisfactory when the studies of the fourth year are elective. If the course of study for all four years is prescribed, I feel sure that the greater part of the teaching of pediatrics should be given in the fourth year, when the students have a better knowledge of internal medicine and of physical diagnosis. In the third year, at any rate at the beginning, they are hardly competent to make the most of pediatrics, especially in its clinical aspects. On this account I feel that in schools in which the fourth year is elective the greater part of the clinical teaching of pediatrics in the third year should be given in the second half of the year. The first half of the year could then be devoted to preparatory lectures and to instruction in the anatomy, development, physiology and pathology of infancy and childhood, providing those subjects had not been taken up earlier in the course. In Harvard, at least, the students are taught little or nothing about these subjects at these ages and are consequently not properly prepared to take up the study of pediatrics. I believe that instruction in these subjects should form a part of the regular courses in anatomy, physiology and pathology. If these departments are not prepared to give such instruction, it should then be given under the direction of the department of pediatrics at whatever time these subjects are taught.

It is very difficult to decide as to the relative proportions of the various forms of teaching which will give the best results. Personally, I believe that there is still room for a moderate amount of didactic teaching in the form of lectures and clinical lectures (amphitheater clinics for a whole class). The reading of textbooks can never take the place of lectures, if they are given as they should be given. The right sort of a lecture can paint a picture of disease, bring out the cardinal points and leave an impression on the mind which no textbook can possibly do. Lectures which are merely a monotonous recital of the author's or someone else's textbook are, however, worse than useless. There are also certain cases with gross lesions which are suitable for demonstration in the amphitheater and which, when shown in this way, save an immense amount of time for the study of the far larger class of cases which require closer observation and individual examination. Recitations are, I think, practically useless. The same result is attained, with the additional advantage that the students are made to think for themselves, by the "case teaching" already described. This form of instruction should, I think, replace recitations and possibly a part of the lectures. It is more valuable toward the end than at the beginning of the course. In any case, the bulk of the instruction should be given in the form of section teaching in the hospitals. This is the only way in which pediatrics, or any other medical subject for that matter, can be satisfactorily taught. There can not be too much of it. In this way alone can the student really learn to know diseases and their manifestations and properly prepare himself to treat them intelligently. The most serious obstacle to this form of teaching is the large number of instructors required and the expense entailed thereby. While this is an obstacle which it is at times difficult to overcome, it does not in any way, however, militate against the value of section teaching and consequently must be overcome, whatever the cost.

In conclusion, the teaching of pediatrics, as of other kindred subjects, will never be ideal until the instructors, or at least the heads of departments, devote their entire time and energy to their teaching. They should not be allowed to see private cases except in consultation and then only after they have given a definite amount of time to their teaching and hospital work. Men can not afford to do this, of course, unless they are paid higher salaries than at present. Living salaries can only be paid, however, when the chairs are endowed. We must look to our wealthy and public-spirited citizens to do this.

Remedy for Furuncles.—Dr. A. G. E. Naylor states in the *Australasian Medical Gazette* that he has found compound tincture of benzoin a specific for all kinds of boils. It is applied freely, around and over the boil, within twenty-four hours of its appearance or before suppuration commences.

THE SPECIALTIES IN RELATION TO THE GENERAL PRACTITIONER.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON LARYNGOLOGY AND OTOLOGY, AT THE FIFTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, PORTLAND, ORE., JULY 11-14, 1905.

ROBERT CUNNINGHAM MYLES, M.D.,
NEW YORK CITY.

It is my privilege to open the Section on Laryngology and Otology of the American Medical Association—a highly appreciated privilege which you have conferred on me by electing me your chairman, and for which I desire to thank you. It is not only a privilege, but an honor which I have done little to deserve, but I will endeavor to show my appreciation by presenting a few suggestions in the course of the customary chairman's address, which I trust will be accepted in the spirit in which they are given, not only by this section, but by the profession at large.

There never was a truer saying than that "the more we learn, the more we recognize how little we know." If this truism holds good in the general philosophy of life, it is applicable with even greater force to any subdivision of human knowledge, and not with the least degree of emphasis to general and special pathology.

No one can justly pretend that twenty years ago the leaders of the medical profession, the lights of learning, were lamentably deficient in a clear perception of philosophic principles; no one will accuse them of purposely and wilfully thwarting the progress and development of the science to which they had devoted their lives; no one will seriously deny that they have honestly and faithfully endeavored to act in accordance with their best judgment, conviction and enlightenment, to the best advantage of the noble art whose interests had been entrusted to their care. The same may also be truly said of the guardians of medical prerogative of all ages, but I select for purposes of illustration the period of twenty years ago, because it is a time of personal recollection, a time of which we can judge by personal knowledge of the conditions and circumstances under which medical lore was dispensed and practiced. With that knowledge of circumstances and conditions before our mind's eye, let me ask you what position did the medical world of twenty years ago occupy toward those branches of the art which this section has adopted as worthy objects of special cultivation, teaching, care and practice. It was a position of utter indifference, and it mattered not an iota whether or not the medical student of that day had absolved the short and elective course in our specialties—the only one available—in order to stamp him a full-fledged physician. It is no use arguing that the time for specialism was not so ripe then as it is now, because we know that since time immemorial the medical profession has recognized the desirability and necessity of allotting the treatment of special ailments to specialists; but the ear, the nose, and the upper air tract were treated like step-children, and it is only in the enlightened days of a more recent past that we condescended to raise them to the dignity of legitimate members of the pathologic family. There would be neither explanation nor excuse for the attitude of former cycles but for the truism which I cited as the introductory remark of my address, that the more we learn, the more we recognize how little we know.

As our knowledge of nose, ear and throat affections increased, as we found that local pathologic conditions were frequently responsible for constitutional ailments.

and that the latter in turn might produce local manifestations, we delved more deeply into special research work. The advent of the laryngoscope, rhinoscope and otoscope enabled us to carry research work and special treatment to hitherto undreamed of perfection; we learned, learned more, and recognized how little we knew; and that was the signal for the evolution of the specialist in laryngology, rhinology and otology.

Has the course of events justified his creation?

Although we, as members of this section, unhesitatingly and decidedly answer this question in the affirmative, there are reflex considerations which we, as members of the medical profession, would do well to heed.

It is unquestionably true that when a man concentrates his best powers, energy and knowledge, all that is in him, on the study and practice of one particular subject, his work will in all probability excel in this particular the work of another man who studies and practices a dozen different subjects simultaneously. It should never be forgotten, however, that constitutional disturbances may produce local manifestations, and that, however expert an otologist, for instance, may be in the pathology of the ear, he would be a poor physician if he resorted to a local operation for the removal of a symptom which the more broadly trained general practitioner would trace to constitutional causes. In other words, general and special pathology must go hand in hand, a fact which, it seems to me, has not been sufficiently recognized or acted on.

As medical specialism in the course of recent years gradually assumed the well-defined shape in which we see it to-day, the general and special practitioner have drifted more and more apart. Ever since the specialist devoted himself to the exclusive cultivation of one particular field, in which he established himself as the supreme authority, the general practitioner—whether he liked it or not—took a back seat in the treatment of special diseases.

This is a perfectly intelligible and reasonable standpoint, so far as large cities are concerned, and also among those physicians who are so situated that they will spend the rest of their lives in a large city, because in large cities neither patients nor physicians will suffer from the arrangement, there being a sufficient number of general patients to keep the general practitioner alive. and a sufficient number of specialists to care for those cases that require special treatment. The question, however, assumes a totally different aspect in small towns or in country districts remote from large centers, where there are no specialists, and where the general practitioner is expected to evince his prowess in every case—from prescribing a powder for a child to performing Cesarean section; and considering that, after all, there are more small towns than big cities, the importance is apparent of including in the training and education of the medical student a fair sprinkling of specialties.

In the present advanced state of general and special medical knowledge it is of course absolutely out of the question to acquire a thorough knowledge of everything, as this would absorb the best part of a lifetime. All that is essential in the various specialties should unquestionably be included in the up-to-date training of students, and it is one of the tasks of the teachers of special subjects to select just that amount of necessary detail which can be usefully imparted to the students without appreciably adding to the burden of their mental exertions. Students should be made familiar with that borderland where general and special pathology stand on common ground, for after all the same principles of medicine and surgery underlie both. While, for example, they should not be encouraged to perform operations for the removal of adenoids with forceps on account of the delicate technic of manipulation, they can be instructed in the safe handling of the Gottstein curette, in tamponing the naso-pharynx, in using the rhinoscopic, laryngoscopic and head mirrors, the tongue depressor, the nasal speculum, in inspecting the interior of the nose and larynx, and, above all, in differentiating healthy from pathologic conditions. They should be trained to know when it is necessary to remove parts of the turbinates and when not.

The student of general pathology should be shown—not merely told—how hemorrhage after rhinologic operations can be quickly arrested by application of firm pressure, and his attention should be called to the importance of using such pressure without loss of time before considerable hemorrhage has had an opportunity to occur. The method of applying such pressure, or of inserting a posterior tampon skillfully and dexterously, should be practiced on the cadaver and not relegated to didactic lectures. Ocular demonstration in the autopsy room or in the laboratory in the special course of instruction in nose, ear and throat affections, is in many cases far superior to mere oral teaching, although didactic lectures. of course, should also form part of the special training.

One of the great advantages to be derived from the inclusion of details such as these in the general curriculum would be that the general practitioner, when confronted with ear, nose and throat troubles, will be able correctly to diagnose the case and to determine whether it is within his sphere of knowledge and ability to treat the patient himself or whether it is necessary to refer the case to a specialist.

Far be it from me to advocate the creation of what has facetiously been termed a "general specialist," nor is it my desire to see a medical student overcrowded with subjects for which he has no practical use, but necessity demands something akin to a general specialist in the country districts. This would be a mistake which Professor Huxley already characterized as a grave offense at a period when the medical curriculum was not so diversified as it is at the present day. However, I do think that we are permitted to reckon with the "unearned increment" in the learning capacity of each successive generation, which means that the student of today is able to assimilate more knowledge than did his forefathers, partly from the increasing superiority of fundamental knowledge, partly from the improved and more systematic methods of communicating scientific subjects; and, while I strongly advocate the cause of the specialist in laryngology, rhinology and otology, with equal earnestness, I demand that the general practitioner familiarize himself with such necessary and uncomplicated details of our specialties as I have enumerated.

There is another branch of the profession in which a more intimate acquaintance with the latter would be a useful and highly commendable achievement. I refer to the military surgeon and the general army and navy physicians, on whom the well-being of the rank and file of the army and navy depends.

It may be necessary, when respiration is impeded, to perform laryngotomy, an operation which, under modern enlightenment, every surgeon, and especially every military surgeon, should be able satisfactorily to perform. Even the division of the cricoid cartilage may be safely combined with the operation in order to enlarge the opening, when necessary. The surgeon should be familiar with all new devices which have stood the test of practice. Thus, instead of blindly groping for the bullet or other foreign invader of the trachea, if properly trained, he would illuminate the trachea on modern principles, and thus contribute to the accuracy, speed and safety of the operation. His special training should include a knowledge of the fact that it is easier and safer to open the trachea above than below the thyroid gland, as in the former case he is less likely to come into collision with the large blood vessels.

Similarly, the experience gained from Japanese surgical successes on, or rather off the battlefield, may well be taken to heart. The Japanese perform no operation whatever on the firing line, except in cases of extreme emergency when there is imminent danger to life from hemorrhage or from other causes. After taking all the necessary aseptic and antiseptic precautions, they leave all bullet wounds severely alone, remove the wounded to the rear and have the satisfaction of knowing that in the vast majority of cases the wounds heal by first intention, without causing any inflammatory or other pathologic conditions.

Not being connected with the military branch of the profession, I do not wish to encroach on the domain of others more qualified, by stating in detail how my suggestion for securing the services of specialists for the benefit of the rank and file could be best carried out, but there is one possibility of facilitating improvements in the desired direction, to which I would like to call attention. It seems to me perfectly feasible, in our large cities, to have military medical specialists, who could be called in whenever expert treatment at the hands of a specialist is of importance. I refer, for instance, to mastoid operations, in which the success depends entirely on the degree of competence and thoroughness of the surgeon, and in which the differentiation between the acute and chronic stages decides the method of operation.

The principles I have laid down in this address are not supposed to apply in a one-sided way to general practitioners only. They hold good, only in reversed application, for the training of the specialist as well. It is a mistake to assume that once a specialist has acquired a thorough knowledge of ear, nose and throat diseases, and their treatment, there is no need for him to trouble about any of the ills of other parts of the body. As I have already pointed out, the affections of special organs stand in close relation to the general functional activity of the body, and by narrowing his views, thoughts and opinions strictly to the details of his specialty, the specialist will promptly lose the all-important, comprehensive view of cause and effect in the mechanism of the human body. Again, the general condition of the body often determines whether or not a certain operation should be performed, whether local or general anesthesia should be applied, and, in the latter case, the anesthetic and the method of administration. For this and other reasons it is absolutely necessary that the specialist should keep in close touch with his professional brethren who have adopted the practice of general medicine and surgery. Both, the general and special practitioner, should realize that they are not contestants for opposing favors, but friends and comrades in the furtherance of a mutual cause, and, in the interest of suffering mankind, they should work together in harmony toward their common goal.

It requires no seer to foretell that a large amount of needless suffering would be prevented and a great many lives saved, if the suggestions I have thrown out were to meet with general approval and adoption. At the same time, in the present state of professional feeling, I see the possibility of difficulties obstructing our path, but those difficulties can and should be removed, as the interest of our patients is the primary and decisive factor, before which everything else—avarice, ambition, and imaginary ethical considerations—ought to fade into nothingness and vanish like a blinding fog before the rays of the sun. The feeling of fraternity between country physician and city specialist is by no means too hearty, but all good and true men, who have the real interest of our profession at heart, should unite in this movement, and, working hand in hand, further their own interests and raise the ethical level of the profession to a higher and nobler plane.

Means should be found for the whole medical brotherhood to be in closer touch, and a bond of union should be established which will make us all feel akin, whether we are country or city physicians, specialists or general practitioners. On these lines the medical organization of this country should be overhauled. Every member of the profession ought to be imbued with the all-pervading idea that he has not got hold of one exclusive thing, but that he dispenses his knowledge and ability in the services of mankind just like any other of his professional brethren. Broad and liberal views and principles should underlie our every thought and action, and if the arguments I have advanced should pave ever so slightly the way for diffusing the salient features of special training among the vast body of general practitioners, and for inducing the specialist unselfishly to reciprocate the latter's attempt at increasing their usefulness, it will mark the dawn of a perfected, idealized, medical organization, and I shall have the satisfaction of knowing that I have contributed my share toward discharging my obligations as chairman of this special section.

A COMMON GROUND FOR MEDICINE AND DENTISTRY.*

FRANK L. PLATT, D.D.S.
SAN FRANCISCO.

The recognition of dentistry as a specialty of medicine by the American Medical Association and the International Medical Congresses, marks one of the happiest epochs in the history of both professions, for it has opened the way for a mutual understanding of conditions and study of theories beneficial to both, and destined to promote in no small degree the health and happiness of the human race.

The goal of both professions is practically identical, embracing as it does, all honorable means for the relief of suffering and for the cure and prevention of disease.

Within comparatively few years, the medical profession has made giant strides in preventing epidemics of plague, cholera, yellow fever and malaria, and is to-day waging a relentless war, and one which will ultimately be successful, against the greatest of all scourges, tuberculosis.

---

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Dentistry is no unworthy member of the great medical family, and many of its best and brightest minds are striving with unremitting toil to find means for the prevention of dental disease, and as their efforts are crowned with one success after another they will have but moved further along the common highway traveled by all the healing arts.

The fact that medical science in its various branches is putting forth its latest, and perhaps its greatest, efforts in the direction of the prevention of disease is the very best evidence of the progress and utility of this branch of applied science.

That such effort is demanded and intelligently received by the public furnishes encouragement for renewed effort, and demonstrates the fact that humanity is gradually coming to believe that the prevention of disease is even a greater and more valuable scientific triumph than its alleviation and cure. Admission of the importance and truth of this growing belief leads at once to the consideration of the subject of this paper.

It is an unfortunate fact that the course of instruction in medical colleges, except in a few instances, does not embrace a fairly comprehensive study of dental pathology and hygiene, for they have a direct bearing on other systemic conditions and play a most important part in the health and development of the individual. It would be well also if more particular attention were paid to the diseases of the eye and ear, and the gastric and intestinal disturbances of infancy and later life, as related to diseased conditions of the teeth and oral cavity, in our dental colleges.

The possession of a more general knowledge of these subjects by the practitioners of medicine and dentistry, combined with a greater sense of the obligation of trained minds to impart some of their learning to those dependent on them and less well trained, would accomplish much toward combating disease and bettering the general condition of the human race.

Considering the fact that human beings have inhabited the earth for perhaps fifty thousand years or more, and also that they have been suffering from various conditions of dental disease ever since Adam cut his teeth, it is astonishing how little general knowledge prevails regarding these organs, so essential to the health, development and appearance of mankind. Scarcely one mother in a hundred knows how many teeth there should be in the temporary set, and still fewer know when they should erupt or when they should be lost; and few, few indeed, are the parents who know that the temporary teeth play perhaps a greater part in the development of body and mind than the permanent teeth, and should receive from the day the first one appears, the most painstaking care tending to their preservation.

That expression so common in dental offices, "Why, doctor, that's only a baby tooth, you don't think that ought to be filled?" should be eliminated from the vocabulary of every parent, and there should be heard in its stead, "Doctor, I want my baby's teeth taken care of, every one of them, just as long as he needs them."

How few people we know who have reached maturity without the loss of one or more teeth. It was "only one tooth" neglected until it ached, and then it was extracted. Only one tooth, but its loss eventually disturbed the arrangement and utility of half a set of teeth. This leads to half mastication and half digestion, and whole indigestion.

Parents of all classes, from the dirty and ignorant to the refined and educated, bring their babies two, three or four years of age to the dentist, with their teeth even at these early ages, in all stages of disease. Some have only a few simple cavities, others have scarcely a sound tooth left; with exposed pulps, putrescent pulps, and even a few alveolar abscesses, discharging perhaps a spoonful of pus a day into the oral cavity.

The mother wonders why the baby does not grow, why he does not digest his food, why he does not sleep nights. The wonder of it is that the baby lives at all, and many of them do not live very long, and the cause of death may be traced right back to the septic condition of the oral cavity, back to the mother's ignorance, back to the fact that no one ever told her to care for her baby's teeth, not even the family physician who was present when the child was born, who attended him when ill during the period of dentition, and who should have known, and who should have seen that the mother knew how to keep the little mouth and teeth clean, and should have taught the importance and necessity for doing so. It is undoubtedly a fact, that many of the diseases of childhood, other than those considered incident to dentition, have their origin in diseased conditions of the oral cavity; including of course, dental caries; and it is no less true that throughout life many neurotic and gastric disturbances may be traced directly to the ignorance and neglect of the sufferer in regard to the care and preservation of his teeth. People, as a rule, do not first demand dental services except for the immediate relief of pain; a few, it is true, have learned by previous sad experience that it is well to consult a dentist once or twice a year to have their teeth examined and treated if necessary; and these few, although they do not know it, have reached an unusually high degree of human intelligence. They are well along on the highway of knowledge leading to that remote but beautiful goal when people will understand that it is wiser to employ physicians to keep them well than to cure them when ill. Since we as professional men know these facts, realize their importance and see every day the sad results of ignorance and neglect, since we know that without good digestion there cannot be good assimilation, and without both, good health and good development, since we know that good digestion depends very largely on a proper supply of good, clean food, passed into the alimentary canal through an oral cavity free from septic conditions and provided with the proper organs for its mastication and insalivation, is it not a duty we owe to ourselves and to humanity to impart this knowledge to those who so sadly need it?

This is the duty first of the physician, for his relations with the family are necessarily more intimate and begin at an earlier period than those of the dentist, and second, of the dentist, for by timely advice he may often prevent a repetition of the trouble in regard to which he has been consulted.

It is on this common ground, the instruction of the public in regard to the value, care and preservation of the teeth, and the prevention of disease, that the professions of medicine and dentistry may join hands and work together for the good of humanity and the honor of themselves.

THE PHYSICIAN AS A DENTIST.*

CALVIN WILLIAM KNOWLES, M.D., DD.S.
SAN FRANCISCO.

The physician has practiced his dental specialty for many years previous to the establishment of a dental college, which took place in about the year 1839. When conditions pertaining to the medical side of dentistry arose, in years gone by, it was customary for these cases to be referred to the medical specialist or general practitioner.

Dental colleges being organized and a more thorough medical knowledge being required, it was not so necessary for the opinion of a medical man in cases which involved the medical side of dentistry.

Dentistry is regarded by some as an art or science, rather than a specialty in medicine, for the average dentist is not a physician, has received no medical education whatever, and practically knows nothing about general medicine, or else has a very superficial knowledge of it. It will be useless for me to discuss or to dwell on this point, as it has been referred to and rehashed for a number of years, without really coming to any definite conclusion in the matter.

Dentistry as practiced by some men is a specialty in medicine. Dentistry ought to be on the same footing as medicine, that is to say—educational requirements, a four years' course and an M.D. Not until these are required, will a dentist be recognized on the same footing as a physician.

Physicians as a rule regard dentists as mere mechanics, or men who have received a smattering of medical education. Do you wonder why we are so looked on!

I am sure it was a great mistake when dentistry branched out for itself, and I am afraid the day is far distant when we are going to shake hands with our brother medicos and be licensed by a medical board, although I hope the day will soon come.

You ask the question: Why should a dentist be a physician? First, because he would have an accurate knowledge of medical science, and would be able to cope with many diseases, and recognize many conditions which he was ignorant of before. Second, when he sees his patient he will recognize his condition, note the condition of the heart, pulse, etc., or whether a contagious disease be present. Third, the benefits from the training he derives and the advantage his knowledge is to his patients.

The advantages of the physician-dentist, as I may term him, are as follows: Being an M.D., he is on a rank with all medical men, providing he is a graduate of a regular recognized medical college, and a licentiate of the state in which he practices.

The prestige which goes with the degree is of value not only in the medical profession but also in the dental. One's knowledge being superior, one's work and one's fees will be superior. People will willingly pay more for the services of one in whom they place much more confidence.

Are not these sufficient reasons for a broader medical education? I am sure that if dentists had the opportunity and could spare the time they would most certainly take a medical degree.

The word stomatologist takes the place of the word dentist in being a newer and more up-to-date one, the use of which has become quite common in the larger cities. By the word stomatologist, we understand one treating diseases of the mouth, and especially the teeth. It perhaps sounds a little more medical than the word dentist, and would fit the physician-dentist a little better than the ordinary word dentist.

In ancient medicine the physician practiced the dental specialty. In an old manuscript consisting of over 100 pages a most interesting account of the anatomy, physiology, medicine, materia medica and therapeutics is given. The following are examples of some of the aphorisms given in the manuscript:

> There are three bones in a man's body, which when fractured will never unite again, and neither of these exists when a man is born, namely, a tooth, the knee pan and the os frontis.
>
> To extract a tooth without pain. Take some newts, by some called lizards, and those nasty beetles which are found on ferns in the summer time. Calcine them in an iron pot, and make a powder thereof. Wet the forefinger of the right hand, and insert it in the powder, and apply it frequently to the tooth, refraining from spitting it off, when the tooth will fall away without pain, it is proven.

Bleeding and local applications, such as poultices and counter irritants, are frequently alluded to. The exact date of the manuscript is not known, but it was probably written about the end of the fifteenth century. So you see the early physician practiced this specialty also.

Dentistry is one of the oldest professions dating from the time when people were placed in front of the temples in order that they might gain relief. All down through the different ages literature has been contributed by the different observers.

Dental surgery has always been associated with education and scholarly men, and not with mere mechanics or tonsorial artists.

Our literature of the present century is elegantly written and illustrated with beautiful pictures, giving in detail the different oral deformities, and the modes of treatment by surgical or mechanical means. In our own United States there seems to have been in the last fifty years a very rapid growth and high degree of development in dental science, as compared with other countries. The percentage of qualified persons practicing dentistry is fully as large as those in other similar callings of life. It is stated that after five years only about 20 per cent. remain in practice, and that the qualified and successful are only about 5 per cent.

Dentistry as a science and art is a noble calling and is worthy of the best efforts and of the finest minds.

THE PHYSICIAN'S DUTY TO THE CHILD FROM A DENTAL STANDPOINT.*

ALICE M. STEEVES, D.D.S.
Dental Clinician to Boston University and to the Dispensary of the Good Samaritan.
BOSTON.

The possibilities for usefulness of the dental profession suggested to our mental horizon make us sigh and wonder if the time will ever come when the laity may receive the proper instruction regarding the real value of the organs of mastication.

Comparatively few understand and appreciate all that the faithful dentist may be able to accomplish.

---

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

But too many either wholly neglect this important subject or, perhaps worse, make the best bargain counter contract possible with the man who guarantees "satisfaction or no money back" until the skillful esthetic dentist cries out, "hideous, all is hideous," "cleanliness next to Godliness" will not be in that mouth.

To whom shall we turn in this hour of doubt? To the vast army of educators, ministers, physicians, teachers of schools, and all public institutions.

But the public educator will tell us that the child must learn to keep his mouth clean at home. Then how are we to use all influence possible to reach that home, while the school officials are becoming educated to this crying need of the age? Many ways suggest themselves, but our nearest relative in the field is the family physician. He it is who welcomes the little stranger into the world, advises the mother on many subjects, and tells the father that such a boy will become a sturdy man. Let us ask our medical brother not to forget those protruding and receding jaws, or that those temporary teeth ought to do duty for a definite period, and that in order that they may accomplish this they should be cared for from the time that they appear as small white pearls above the pinkest of gums (let us hope that the gums are as pink as they should be) and that the loss of one single tooth means quite as much to the superstructure of that face as a sill from the side of a house. More than this, the teacher must present a clean, wholesome mouth else his instruction will be without effect. It is example as well as precept that tells.

We would also urge in their contact with other educators not to lose sight of the fact that the care of the mouth ought to be included with the hygiene of the body.

The many medical specialists owe a duty to the race. A case of gastritis treated without first cleansing the mouth and its contents, certainly not! The laryngologist in operating for adenoids must realize that often sufficient bacteria may be found in a single tooth cavity to infect a whole regiment of soldiers, providing an open wound is convenient as a culture medium.

Our friend the orthopedic surgeon has opportunities for good which are unexcelled; what an array of faces for beautifying! How much real good could be done! When, O when will all crooked faces become straight?

It would seem as if the physician in many instances needed more than a gentle reminder, for I find in looking over literature on diseases of children that the reference to teeth consists chiefly of the physiology of development and dentition, while the neglect of cleanliness and deformity caused by too early extraction is condemned in one instance only, and the very important item of correcting deformities from causes either traumatic or congenital is overlooked entirely.

Oppenheim speaks of the unsatisfactory information to be found in medical text books, but does not improve matters much. He emphasizes, however, the fact that it is unsatisfactory. Koplik points out the effect of malnutrition, syphilis and nervous irritation. Doukin describes the pathologic conditions commonly supposed to be due to dentition. Rotch refers to development and dentition. Holt goes into the physiology and pathology from malnutrition. Jacobi speaks of the pathology of dentition and cautions against too early extraction, and Starr refers to development and dentition.

355 Boylston Street.

THE MEDICAL RELATIONS OF CERTAIN CONDITIONS OF THE MOUTH.*

L. DUNCAN BULKLEY, A.M., M.D.
Physician to the New York Skin and Cancer Hospital, Consulting Physician to the New York Hospital, etc.
NEW YORK CITY.

Although not specially occupied with disease of the mouth, I have such frequent occasion to inspect the buccal cavity in connection with dermatologic practice, that I have become very much interested in the subject. It also happens that many cases of disease of the tongue, gums, and buccal mucous membrane are sent to me, and many occur in my own practice.

The mouth occupies a very prominent place in the economy, as the point of entrance of food, and I need not, in this audience, dwell on the importance of having it, and all within it, in a proper condition. Few, among the laity at least, recognize fully the essential part which is played by the mouth and its appendages in the process of digestion, and consequently in the life and health of the individual. Mastication and proper insalivation are the first steps in digestion, and undoubtedly much ill health often results from the improper manner in which these are performed. I am convinced, from long observation, that hurried eating, imperfect mastication, soft food, and the taking of fluid while eatables are in the mouth, are fertile sources of trouble. This is a matter concerning which physicians and dentists should educate their patients. In this connection, of course, dentists render incalculable service, in placing the teeth, whether natural or artificial, in a condition suitable for their important work. As an illustration from the animal world, I may refer to the sometimes marvelous effects in poorly nourished horses, resulting from filing down the back teeth, as I have repeatedly observed in my own animals.

Incidentally, I would like also to mention the very great advantage of thorough mastication in sea-sickness. When other food will not remain in the stomach, one can often retain crackers or dry toast, thoroughly chewed and moistened only by the saliva, and it is a constant direction of mine to sea-going patients that these be so eaten while in bed; the mouth, though dry and parched, will in time moisten this food, and when thus thoroughly chewed the stomach seldom rejects it.

In considering the mouth, I have often been struck by the remarkable vitality of its tissues, which I think we hardly realize. Many times a day they may be subjected to repeated irritation from various foreign substances, or to mechanical damage, and yet how seldom are they permanently injured! The powers of healing of the buccal cavity sometimes seem to put all theories of surgical asepsis to naught. Bacteriologists tell us that a dozen or two different micro-organisms can always be found in the healthy mouth, and yet, somehow, none of them seem to exert a harmful influence in regard to the repair of injuries, even when pus, and presumably its coccus, is present. Witness the prompt healing after the extraction of a tooth, or even after the most serious surgical operation; and how rapidly a burn from hot food or drink, or from smoking, is healed. Surely nature has made wonderful provision to guard the portal through which the sustenance of the individual must pass, for many years.

The explanation for this is found, in part, in the character of the saliva, as it is proper to designate the combined secretion of the various glands opening into the buccal cavity, including those of the mucous membrane itself; of all of which we know far too little. Like all other animal secretions, the saliva undoubtedly varies materially under different circumstances. We all know well the excessive and watery secretion, induced by pilocarpin and occurring in mercurial salivation, and the diminished secretion caused by atropin. Nervous causes may also at one time produce a free flow of saliva and at another may almost arrest the secretion, and leave the mouth dry and parched, as may also febrile diseases. The effects of food are also well known and the expression "making the mouth water," is often used in regard to certain appetizing articles.

---

* Read in the *Section* on Stomatology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

How far or in what manner chronic disordered states of the system affect the saliva is not known with any degree of certainty, but that they do have some effect is beyond doubt; anyone who has had much to do with patients suffering from many minor or gross ailments, will testify to the constant mention made of the condition of the mouth. The saliva is often spoken of as thick, viscid, sticky, or pasty, and the taste as sweet, sour, bitter, or offensive, while the expression "a dark brown taste in the mouth" is very common in New York, at least.

Last year, Drs. Stern and Lederer[1] presented before this Section the results of some observations and studies on changes in the salivary secretion affected by systemic disease, which while perhaps not so accurate and complete as could be desired, are certainly a step in the right direction. Thus, in diabetes they found the saliva to be acid, in about one-third of the cases, and detected glucose in over one-half of them. In uricacidemia, the saliva was alkaline in nearly nine-tenths of the specimens, and uric acid was demonstrated in nearly one-third of them. In acute gastritis, the saliva was acid in 8 cases and alkaline in 20; in hyperchlorhydria the saliva was acid in nearly 40 per cent of the cases, alkaline in about 22 per cent., and amphoteric in over 35 per cent., and in hypochlorhydria the saliva was acid in 2 cases, alkaline in 15, and amphoteric in 6 cases. The acidity was found to be due to lactic acid, or to acetic acid.

While these studies do not by any means cover the whole ground, or even a very small part of it, they are, as just remarked, a step in the right direction, and should serve as a stimulus to others to corroborate or to add to them. Unfortunately, I cannot contribute any exact data in this direction. I have occasionally tested the secretions from the mouth in patients exhibiting marked acidity of the system, and have found them acid, sometimes neutral, or alkaline, but I have not kept records which can be utilized, so that I can speak only in a general way, hoping sincerely that those who have more time, or determination, will investigate the matter and give us scientific data to build on.

As already stated, the saliva undoubtedly varies in quantity and quality under different circumstances, and physiologists tell us that the total daily average secretion, in health, is from two to three pints. The solid ingredients vary according to different analyses, from 3.5 to 11.7 parts per thousand, and the salts from 1.03 to 2.2 parts per thousand. It is interesting to note, that while an analysis of the ash from saliva showed nearly 50 per cent. to be potash and nearly 10 per cent. soda, with a number of other ingredients, but no calcium, an analysis of the so-called tartar on the teeth showed that "the chief part of the inorganic constituents consists of calcium carbonate and phosphate," with some 20 per cent. of organic matter.[2]

All of us realize that different changes take place in the mouth at different times, but, so far as I know, no clear or definite knowledge exists as to the conditions causing them. Time and again decay in the teeth starts up suddenly, or the teeth are found unusually soft or eroded or tartar collects very rapidly, or a pyorrhea alveolaris occurs, etc., and no adequate cause can be determined with certainty. It is easy to ascribe these and other conditions to the action of micro-organisms, which undoubtedly have their share in the work, but we must remember that the buccal cavity is continually full of innumerable varieties of these, and more modern sciences, in various directions, teaching that microbes can not develop and become operative except in a suitable soil.

We must look, therefore, to the constitutional condition of the individual, as modifying the saliva, or soil in which the micro-organisms are bathed, and which in perfect health seems to possess such a marvellous power of protecting all within the buccal cavity from the inroads of bacterial life; even as the phagocytes in the blood guard the general system.

It is, of course, a common observation that debility or exhaustion of any kind often leaves its imprint on the structures within the mouth, as elsewhere. The less vital resistance there is in the tissues, the more readily do they yield to microbic invasion.

Dyspepsia is undoubtedly a fertile source of trouble in the mouth, as is constantly observed in the case of so-called "canker sores," and decay of the teeth may continually be found to vary with the condition of the stomach. In the studies referred to by Stern and Lederer,[1] in acidity of the stomach the saliva was found to be acid in nearly 40 per cent. of the cases.

The acid condition of the system associated with gout, rheumatism, and rheumatoid arthritis also has an effect on the teeth and gums, as I have witnessed time and again, in many cases of pyorrhea alveolaris, some of which I have watched for considerable periods of time. The disease has varied immensely at different times, according to the acidity of the system, often as indicated by the urine, and in many cases I have seen the very greatest benefit result to the condition of the teeth and sockets from a purely antacid treatment. We all recognize the value of alkalies locally in the mouth, and the injury from acids.

In the light of what has been said, should not the dentist, who is primarily responsible for the mouth, seek the aid of the physician in connection with many of the conditions about which he is consulted? Even as the physician recognizes the need of special skill in dental matters, and advises patients to seek it.

The subject of diseases of the mouth is a very large one, and can hardly be touched on now, but it is such an important matter, and dentists so often have the opportunity of seeing these affections early, when much can be done by proper treatment, that a few words may be of service.

---

[1] Stern and Lederer: The Journal A. M. A., Dec. 10, 1904, p. 1765.

[2] Hammersten: Text-book of Physiological Chemistry, New York, 1898, p. 281.

Syphilis is, of course, the most frequent cause of lesions within the buccal cavity, for few patients with this disease escape, at one time or another, from having some affection of the mucous membranes occasioned thereby: For many reasons, therefore, it is very important that dentists should appreciate and be able to recognize the effects of the disease in this location. This, of itself, is a very large subject, on which I have twice addressed the dental profession,[3] and which cannot be fully considered now. I must earnestly utter the warning, however, that dentists should be extremely cautious, whenever there are sores, even though they be very superficial, on the lips, tongue, or buccal mucous membrane, and that if not quite certain as to their character, they should seek competent advice before exposing themselves or their other patients to the dangers of syphilitic inoculation. As I showed in the first paper alluded to, there are many instances on record where this has occurred, and, of course, multitudes which have never been reported in the journals.

Aside from canker sores, from disordered digestion, leukoplakia is probably the next most frequent condition of disease found in the mouth, chiefly in men, and principally in those who use tobacco. This is commonly a harmless affair, though it may be the starting of an epithelioma, especially if it has been injudiciously treated. It will sometimes give trouble by mildly unpleasant sensations, and often perplexes the physician from its resemblance to some of the lesions of syphilis. Many a patient has long been under antisyphilitic treatment uselessly because of the persistence of this relatively innocent local affection, leukoplakia, which has no connection whatever with syphilis.

Epithelioma is the most important disease of the region of the mouth, and elsewhere, and it is in connection with this often lamentable affection that dentists can frequently be of the most efficient service, in many ways.

In a considerable number of cases of epithelioma of the tongue, and sometimes in that of the inside of the cheeks, the disease has started and is often kept up by irritation from sharp, rough, and decayed teeth, and from amalgum fillings, and these should all be sedulously looked to and corrected. Also, when there is any process suspected to be epitheliomatous, the patient should be urged to seek competent medical advice; for we know that while this disease begins as a purely local process, by neglect or by continued irritation it becomes deeply seated, the glands become infected, and often it is well nigh incurable. Happily, the former custom of touching all such sores with nitrate of silver or some other caustic is no longer largely practiced, but I must again raise my voice earnestly against all such meddlesome practice; for in times past I have seen many epitheliomata which had been thus goaded on until their condition was very serious.

Lupus also sometimes affects the gums and palate, but this is a disease which is so very rare in this country that it is hardly to be considered. It commonly exists elsewhere, especially on the face, before attacking internal tissues.

Localized tuberculosis, however, is not so very infrequent in or about the cavity of the mouth, and it is not infrequently mistaken for a syphilitic manifestation. Patients should be warned against neglecting this.

There is one more aspect of the medical relations of certain conditions of the mouth which I would like to mention before closing, that is the effect on the general system, or on special portions of it, in a reflex manner or otherwise, from error or disease in the teeth or jaws.

We all recognize the harm done to digestion by bad or imperfect teeth and have seen the great benefit to the general health resulting from a proper repair and adjustment of the organs of mastication, so that this process can be perfectly performed. Numberless instances are on record, and we must all have seen cases, where some error in the teeth and jaws has caused reflex disorder, headache, neuralgia, etc., which have ceased when the trouble has been rectified. Hence, the physician has frequent need of the dentist, and should ever bear in mind the assistance which can be obtained in this direction, in obstinate cases.

Finally, purulent discharges in the mouth, as from abscesses or from pyorrhea alveolaris, etc., passing into the stomach, have a more or less disturbing influence on digestion and nutrition, and should be corrected for this reason, if for no other. The same is undoubtedly true in regard to the results of decomposition of food lodged between the teeth, and from mouths not perfectly cleansed, one or more times daily. We all know the dreadful condition into which the mouth sometimes gets in acute or febrile diseases, with sordes on the teeth, and it is a question if some of the unpleasant general symptoms occurring in these cases are not caused by the gastric or intestinal fermentation thus set up. It seems certain that some of the discomfort to the patient, and possibly even some serious complications could be avoided if more attention were paid to antisepsis in the mouth at these times, when it is notoriously neglected.

I have jotted down a few of the many thoughts which have come to me, from experience, in the hope that a discussion of some of the points suggested may result in a more careful and complete consideration of the medical relations of certain conditions of the mouth.

531 Madison Ave.

DISCUSSION.

ON PAPERS BY DRS. PLATT, KNOWLES, STEEVES AND BULKLEY.

Dr. Vida A. Latham, Chicago, said that her experience in the last few years has been that the conditions of the mouth and teeth are based almost entirely on systemic conditions. One of the great objects of the work of this section is to try to show a relationship between the system and the teeth and adjoining structures. To her mind, syphilis has much to do with the condition of the mouth. She said that she has seen cases in her practice in which syphilis had been contracted, and in which the teeth before infection had been in splendid condition, and afterward discoloration, decay, erosion and abrasion have been marked, with interstitial gingivitis resulting in pyorrhea alveolaris and wasting of the alveolar processes. Dr. Latham said that saliva is a physiologic secretion, and it will remain for a specialist to work out the relationship between pathologic conditions of the saliva and constitutional diseases. In the last two years Dr. Latham has had two cases of gonorrheal infection of the mouth—the only two that she has ever seen. They were demonstrated by microscopic examination, and it was proved conclusively that they were due to infection from the fingers—uncleanliness—rather than from systemic cause. These cases were unusually peculiar. There was marked inflammation with much pain, the teeth became loose, there was a greenish, slimy condition of the gums, and there was slight fever.

Dr. M. I. Schamberg, Philadelphia, said that during the past year he had seen just such cases as Dr. Bulkley had mentioned. He saw one case of lupus, several cases of carcinoma of the mouth, and in one case the main interest lay in the early diagnosis. The dentist who referred the case to Dr. Schamberg did so because he was rather doubtful as to the condition. Microscopic examination of the growth, which was very slight at the time, showed it to be an epithelioma. It was treated by the *x*-ray, and an absolute cure took place. Several cases of syphilis of the mouth in various stages have come under Dr. Schamberg's care during the past year. The last case was an initial lesion immediately posterior to the superior central incisors. The case had gone on with a wrong diagnosis for three weeks, both the physician and the dentist failing to discover the cause of the lesion, and the condition was pretty bad. Dr. Schamberg questioned the patient as to possible inoculation, and also as to whether there was any eruption on his body; until he examined the body himself no thought of secondary eruption had been suggested, but he found a very pale, macular syphilid on the abdomen, which decided the case. The mouth lesion had been masked by the application of caustics and other forms of treatment. Such cases show the necessity for thorough insight into medicine generally, and also that the general practitioner is too frequently derelict so far as studies of the mouth are concerned.

---

[3] Bulkley: Dangers Arising from Syphilis in the Practice of Dentistry, Internat. Dental Jour., August and September, 1890. Manifestations of Syphilis in the Mouth, Trans. New York Odontol. Soc., 1898, p. 11.

Dr. G. V. I. Brown, Milwaukee, said that the value of the dentist's work lies in being able to diagnose cases early. He referred to Dr. Bulkley's statement that the most frequent cause of lesions within the mouth is syphilis, and said that it is a difficult matter for those who deal with the lesions and do not treat syphilis in any sense except when forced to do so to decide whether or not the lesion is syphilitic. He is inclined to believe that syphilis as an etiologic factor *per se* is greatly over estimated. In some papers Dr. Brown thinks that too much emphasis has been laid on it. There are many cases in which a diagnosis of syphilis has not been made, and in which the one thing the patient needs is the proper treatment for syphilis, without which, of course, other measures would not only be useless, but would probably result in serious injury to the patient. On the other hand, Dr. Brown [illegible]d that frequently time is wasted in endeavoring to over[illegible] systemic conditions which do not exist, when simple, [illegible]rect, prompt, surgical treatment is required.

Dr. M. L. Rhein, New York City, stated that he had occasion last year to take exception to the name of saliva as applied as being misleading. There are in the mouth the submaxillary glands, the sublingual glands and the parotid glands. It is true they are the salivary glands of the mouth, and that they give forth a large percentage of the fluid that circulates in the mouth, but added to these there are all the eliminative secretions of the mucous follicles, which add materially to this fluid. Up to the present, this portion of the fluid has had no recognition given to it as having any of the function that pertains to salivary glands, and it is for this reason, Dr. Rhein said, that exception should be taken to the use of that term. He declared that he knows that a great many workers take exception to this criticism, and prefer to use the word "saliva" as it has been used in the past. Dr. Rhein agreed with Dr. Bulkley in his explanation of some of the lesions of the mouth and said that the great trouble is that the majority of physicians have no knowledge regarding the normal physiologic condition of the mouth, and consequently when they examine an abnormal mouth they are at sea in regard to making a proper diagnosis either of what may be wrong, or as to whether it is even abnormal as distinguished from physiologic. He said that he has had most startling experiences of this kind, and finds that the medical text-books on this subject are almost of no value. In most instances, the conceit of the average medical teacher carries him past this important specialty. To illustrate the average medical man's idea of the mouth, Dr. Rhein told of a patient who presented himself last fall with lesions in his mouth that Dr. Rhein had no hesitancy in diagnosing as marked leukoplakia, and of such a nature that he thought there was strong suspicion of syphilitic etiology. He found that the physician under whose care the patient had been for a number of years had overlooked important facts; he seemed to have paid no attention to the patient's history of losing his hair about five years previously and to other symptoms. On the physician being requested to look into the mouth symptoms, he informed Dr. Rhein by telephone that it was simply an inflammatory condition, and that in a few weeks the patient would be perfectly well. Six weeks later the patient had not only not been cured, but the symptoms had increased in severity; there was an active pathologic condition present that was so apparent that Dr. Rhein refused to have any further connection with the case unless some attention was promptly given to the general condition, and when he again called the physician's attention to the patient he finally took him to another practitioner who at once confirmed the diagnosis of leukoplakia of syphilitic origin. The patient was placed on antisyphilitic treatment and the symptoms were decidedly ameliorated. Dr. Rhein believes that a large proportion of cases have a decided cause of this nature. The trained stomatologist has opportunities for the minute and careful observation of what he sees in the mouth that so educates his sense of perception between the various conditions that it places him in a peculiarly fortunate position as regards diagnoses. He believes that there is no gainsaying the fact that has made the value of the dental services to the public at large in this country of inestimable value as compared with what they have received in other parts of the world, and that is the absolute thoroughness of the work. Dr. Rhein said that there is no reason why the highest scientific utilization of research work of all that we can gain in medicine should not be put to advantage in what is apt to be described at times, and that is the handiwork of the dentist, and he protested against taking one iota of credit from the value of that handicraft.

Dr. Duncan Bulkley, referring to stomatology vs. dentistry, said that physicians do not have to do with the teeth entirely, but with a thousand other things as well. Stomatology, he said, is of very great advantage, and if that can be introduced everywhere I think it will be a step in advance. He agreed with Dr. Brown that one thing must not be praised to the disparagement of another. American dentistry is recognized all over the world. There are many cases of pyorrhea alveolaris which it would unquestionably be folly to send to a physician. In those cases which have been under his care he has used peroxid of hydrogen freely. Undoubtedly, the first item is proper surgical treatment and perfect dental cleanliness. On the other hand, he asked why a patient has this condition; it is not from the parasites in the mouth. In reference to the saliva, he said that nine-tenths of it is made from the three groups of glands, but the mucus must, of course, be counted. He did not agree with Dr. Rhein as to using the word "eliminative." There is no reason, he said, to believe that these glands of the mouth have any eliminative function; it is simply a moistening process. He called attention to the fact that some of the best dentists are studying and have studied medicine since they began practicing, and are now graduates in medicine. All branches of medicine should be co-ordinate.

Dr. Bulkley said that he still holds that almost everybody who has had syphilis, at some time or other, has had mucous patches; he has had some patients who have been infected from soiled instruments. He has seen chancre in almost every part of the mouth and tongue. He also stated that he has seen many cases of wasting of alveoli. In time gone by it was supposed that mercury did this, and it created a great furore against mercury. He asked how many physicians have reason to believe from their experience that mercury does salivate. Dr. Bulkley has not yet found cases in any number in which he thought the mercury was responsible. He has had cases with syphilitic alveolar trouble. He said that he does not know anything about the saliva in syphilis—whether or not it is modified, though he is sure that it is altered in syphilis. The saliva is not an excretion; it is a secretion, and that secretion can be altered by disease. He has never happened to come across any cases of gonorrhea of the mouth. He distinguishes between leukoplakia and syphilis. Legally, one does not speak of syphilitic leukoplakia any more than of syphilitic psoriasis. Leukoplakia is one thing and mucous patches of various degrees are another. There is a great deal of leukoplakia sometimes from smoking and from unknown causes, which he is sure is not syphilis. The diagnosis is often very difficult. He concluded by saying that we are just entering on the right aspect of what has been called dentistry.

EARLY DIAGNOSIS OF SURGICAL DISEASES OF THE URINARY TRACT.*

BENJAMIN TENNEY, M.D.
Assistant Surgeon Boston Dispensary.
BOSTON.

For the purposes of this paper the urinary tract will be limited to the kidney, ureter, bladder and prostate. The prostate, although essentially a genital organ, when diseased, interferes more with the urinary function than with the genital function, and must not be left out of account in any discussion of the urinary tract.

That early recognition of diseased conditions in these organs makes the desired "cure without undue risk, delay or pain" more often possible needs no argument, and to the physician who uses his trained brain, fingers and eyes, especially if he has access to a good microscope, there is little difficulty in recognizing the indications for further careful investigation of the urinary tract by the most modern methods of special diagnosis.

Interesting as these special instruments are, and fascinating as is their use, this paper is to deal briefly and solely with the indications which should lead to the employment of one or more of them.

In order to obtain some idea of the frequency of diseases in these organs as compared with general surgical diseases, the annual reports of the Massachusetts General and Boston City Hospitals have been taken for the last five years. During this period there were over 35,000 cases in the surgical beds of the two institutions. More than 1,100 of these are said to have presented some lesion of these organs, being about 3.1 per cent. of the total surgical admissions. The prostatic diseases lead, with 427 cases; the kidney follows, with 373 cases; the bladder next, with 304 cases, and the ureter last, with 7 cases. The grouping in this table is my own and requires further evidence before it is fully accepted, though it is in accord with the more recent theories.

SYMPTOMS.

Most patients with disease in the urinary tract consult their physician on account of one or more of three conditions. First, localized pain; second, altered function; third, hematuria. When all three symptoms are present, there is hardly a doubt of the presence of some definite surgical condition in the urinary tract.

That there may be some condition outside which reflexly excites symptoms is indicated by a case recently seen with Dr. Mitchell of Portland, Maine. Dr. Mitchell had done a complete and satisfactory perineal prostatectomy a few days previously; the healing was perfect and urethra free, but the man continued to have pain referred to his bladder, and he urinated every half hour. Naturally, blood and some pus were present in his urine. Finding tenderness over the right kidney and along the ureter, I suggested exploration, but both kidney and ureter were found to be normal.

At autopsy two months later, a bony tumor of the bodies of the lumbar vertebræ was found, not causing direct pressure on either kidney or ureter, but presumably irritating the nerve supply of the bladder. This combination of conditions is so very rare that it may be disregarded in making a preliminary diagnosis.

When any two of these symptoms are found, I believe that all surgical conditions in the urinary tract should be ruled out before attention is directed to other organs, or the patient is left to Nature somewhat upset by the various so-called urinary antiseptics and sedatives.

"Other diseases" includes all cases with diagnosis of hemorrhage and others without definite diagnosis.

Of the single symptoms pain is of little value in directing attention to the urinary tract, and the great majority of pains without disturbance of function or blood in the urine will be found to be caused by some other organ or system.

---

*Read before the Surgical Section of the Mass. Medical Society, June 13, 1905.

Disturbance of function is almost worthy of being called pathognomonic. The normal adult individual, under average conditions of heat, excitement and drinking, empties his bladder from four to seven times a day, and should be able to sleep seven or eight hours undisturbed. There should be no difficulty, discomfort or urgency about the act. Regular variations from these habits are the first of all symptoms to appear in several urinary diseases and must be inquired into carefully and regarded with grave suspicion when persistently present.

Hematuria always means something wrong in the urinary tract and when persistent or when recurring intermittently it should lead to careful study as to its source and cause, not because the loss of blood is always dangerous, although it may hasten the end in some conditions, but because it is almost invariably an indication of some serious and possibly curable condition.

It is possible for a patient to have some surgical disorder of the urinary tract in which none of these symptoms appear for months, but under continuous observation something will be found if these organs are kept in mind.

So far as I have been able to look up records, there is only one of these surgical conditions which may not be found at any age. Infants and children have been reported as having movable kidneys, calculi, malignant growths, and in fact all these diseases except prostatic hypertrophy.

Beyond the fact that most of the movable kidneys recorded are female and all the hypertrophied prostates male, either sex may suffer from any of these conditions.

Instead of discussing the symptoms of each disease separately, I have grouped the most important symptoms and attempted to show why they appear under different conditions.

PAIN.

Pain from disease of the kidney may be felt at the point of injury or may be referred to the opposite side or to some distant point. Any mechanical condition which interferes with the outflow of urine, such as a kink in the ureter, or stone, or clot, or swollen lining, *or tumor pressure, or stricture, or ligature, which prevents* the free flow of urine from the kidney, will cause pain varying in degree according to the location and character of the obstruction. The same sort of pain may be felt in certain infections of the kidney in which the bulk of tissue within the capsule is increased, or in which there is hemorrhage under the capsule, or after artificial distention of the pelvis.

As has been previously pointed out, there are some observations which go to show that the kidney is extremely tolerant of all conditions which do not stretch its capsule, and that simple slitting of this capsule for a time will relieve the pain of pelvic distention, even when caused by stone in the ureter. How much, if any, sensation is possessed by the kidney beyond its reaction to capsular stretching or to what is sometimes called internal pressure I do not know.

Many malignant growths cause no pain for a long time, especially in children. The same is true of some renal calculi, but just as soon as a blood clot or fragment of tissue, or bit of calculus plugs the ureter, the tynkoplakittack of pain begins.

strong suspi of a normal kidney, even if considerable physician und. causes no pain; packing, washing out or ber' of yeadrains in the pelvis causes no pain in an exposed but uninfected kidney. Possibly its only sensory nerves lie in the capsule or walls of the pelvis. Of this we ought to know more.

have paid

If there is any characteristic of pains arising in the kidney it is their radiating character. They may be referred to any point between the shoulder and ankle on the same side, to the region of the opposite kidney, to the pelvis, or to the abdomen generally, and all at the same time.

Pain in the ureter is produced by stretching or distention. Passing a ureteral catheter into a normal ureter, even if purulent urine is flowing through it, causes less pain than passing a soft rubber catheter into a urethra. Apparently there is little sensation except that of tension in any case, but this may become extreme pain when a concretion is being forced down by the peristaltic contractions.

There is no possibility of being sure whether a pain which a patient describes is due to a renal or to a ureteral condition without other evidence. The patient's sensations may be precisely the same in either case. The bladder is not sensitive unless inflamed, and then it tolerates catheters and drainage tubes which are not moved about. Most of us are aware of the location of the dull ache of an acutely distended bladder, yet many patients carry from a few ounces to some pints of urine constantly without being conscious of it. From one woman who was not suffering very greatly I drew six quarts and half a pint of urine within one-half hour, and this is much below the greatest record.

Some patients with tuberculosis and new growths in the bladder suffer very little during the early stages, when radical treatment may be expected to produce the best results. One of my patients with cancer of the bladder had pain only on urinating until the growth reached a size which mechanically obstructed the urethral orifice. Many patients with calculi are reported to have suffered little until the bladder mucosa became damaged and infected.

In prostatic cases the patients suffer pain like that in kidney disturbances caused by stretching of the capsule in acute inflammatory conditions and from the secondary changes which occur in the obstructed bladders. Pain from prostatic trouble alone is usually referred to the rectum, glans penis, or perineum. When the bladder is involved there is the local discomfort before referred to, and often the almost constant tenesmus due to irritation at the orifice of the bladder and in the prostatic urethra which may amount to pain.

Of the diseases presented in the cases from the two hospitals, those representing acute infections are most likely to cause constant pain, those representing or producing foreign bodies, such as calculi, or clots of blood or pus, or good-sized fragments of tissue almost always produce intermittent pain, while the new growths may be painless for years.

In a general way, pain is more likely to be referred to a point below its origin than above it, but disease of the lower part of the tract is so likely to lead to infection or to painful distention above it that there is always a possibility of being led astray.

ALTERED FUNCTION.

Somewhere I have read that the act of urination begins with a pull of the ureteral muscle fibers which bound the trigone and are continued into the verumontanum of the prostatic urethra or to a corresponding point in the female urethra.

This muscular pull opens the internal orifice and allows some fluid to trickle into the urethra. The voluntary sphincter may now contract and force the fluid back for a time or allow it to pass on. If this description be correct, and I know of no anatomic, experimental or personal reason for doubting it, it explains how the function may be altered by conditions remote from the bladder.

Frequency.—Frequency of micturition may be increased by any condition which diminishes the capacity of the bladder or causes irritation of these lower ureteral fibers.

In cystitis, therefore, when the capacity of the bladder may be reduced to a few cubic centimeters, in tumor and calculus cases in which there is constant irritation of the trigone, and especially in the occasional acute inflammations which accompany an enlarging median lobe of the prostate, and which directly affect these fibers, we may expect increased frequency of micturition. To explain its occurrence in renal and ureteral conditions, it is only necessary to recall the continuity of the ureteral fibers from the kidney pelvis to the verumontanum or the corresponding point in the female urethra.

We have all known the frequent dribbling overflow of a distended bladder to be mistaken and treated—or neglected—as an "inflammation of the bladder" or a little "kidney trouble." There is no excuse for a physician's making an error of this sort. He has no right to guess when he can find out.

Urgency.—Some individuals find it impossible to resist the impulse to urinate. If they attempt to prevent the flow, they leak. In every case there is an uncontrollable contraction of the bladder, due possibly to irritation of the lower ureteral fibers, to a calculus in the ureter or bladder, to a new growth in the bladder, to an enlarging median lobe of the prostate, to an inflamed condition of the urethra nearest the bladder outlet, or else to an incompetent voluntary sphincter, any of which conditions may disturb the normal relation between bladder capacity and contraction.

I have seen examples of all these conditions and doubtless there are others that will produce the same symptom. It is too suggestive to be neglected and must bear an intimate relation to

Incontinence.—Except in the overflow of distended bladders and as it may suggest search for and removal of all irritations wherever found, incontinence of urine has no surgical significance in this paper.

Difficulty in Urination.—This is perhaps as common a symptom as any and results from either mechanical obstruction or from some fault in the nerve supply. It occurs in conscious patients with paralysis of the abdominal muscles and competent sphincter, as well as in those who are in a comatose or delirious condition.

My observation has led me to believe that paralytic and comatose patients are quite as apt to be incontinent as to have retention, unless there is some obstacle which they had previously been able to overcome by voluntary abdominal pressure.

The mechanical obstruction of which we hear most to-day is the hypertrophied prostate, and while unable to discuss it as I should like, I would remind you that it is not a disease of advanced life exclusively. Several cases have been reported in the thirties, and between forty and forty-five the number of men whose prostate begins to produce some discomfort and residual urine is very considerable.

Anuria.—This may occur in the course of certain acute diseases, as a result of some forms of poisoning, after trauma to the urinary tract below the kidney, or to the kidney itself, from vaguely understood reflex disturbances outside the urinary tract, and from any condition which mechanically obstructs the flow of urine into the bladder. The last group of cases is not always easy of separation from the others. Fortunately patients usually go from two to five days before symptoms of uremia appear, and this allows sufficient time, if properly used, for decision and for operative measures if necessary. Absence of urine in the bladder during twelve consecutive hours, if proved by a catheter, may well arouse grave apprehensions, and twenty-four hours is a limit beyond which the responsibility lies very heavily on any single practitioner.

HEMATURIA.

Red blood may show in the urine in amounts recognizable to the naked eye, with or without clots, or in such quantity as only to be recognized by the aid of the microscope. In either case, it may be intermittent in appearance, but in the first case blood is likely to be found on microscopic search long after it has apparently disappeared.

While it may come from any part of the urinary tract and from several causes, persistent or recurring hematuria is so strongly suggestive of a new growth that, next to anuria, it is the gravest single symptom of all.

According to Albarran, hemorrhage was the first symptom in 78 per cent. of 140 malignant bladder tumors and was present at some period in nearly all. According to Israel, 70 per cent. of 66 malignant renal tumors were first indicated by hemorrhage, and 93 per cent. showed it at some period. Deneclara, in 168 cases of tumor of the kidney in the adult, found that hemorrhage was the first symptom in 69 per cent. Even under exceptionally favorable conditions the cause and source of the hemorrrhage may remain in doubt for years.

A patient of mine had hematuria for three years without renal symptoms or palpable tumor. There was no loss of weight or strength and he was particularly active physically. He had a slowly growing prostate with considerable swelling and redness of the median portion, as seen through a cystoscope, which was supposed by one of our most experienced men as well as by myself, to be the source of the hemorrhage. A third surgeon, seeing him six months later, found a distinct renal tumor and a hypernephroma at operation. This experience has taught me never to accept a probable cause of hematuria without ruling out other possible causes.

While hematuria may possibly be due to some harmless condition, its almost constant association with malignant disease and calculi, make it, to my mind, quite as grave, though not so urgent a symptom as anuria of a few hours' duration.

All writers agree that blood in the urine appearing without reference to any physical violence, exertion, or jarring, is very suggestive of new growths. When the hematuria follows such violence, even if slight, they consider it more probably due to the presence of a calculus. In either case it is a hematuria.

If there be also a pyuria, the diagnosis is complicated by an infection which may wholly account for the hematuria or which may be a secondary process grafted on to the original disease.

Continuous or Recurring Discomfort.—This brings

Disturbance of function is almost worthy of being called pathognomonic. The normal adult individual, under average conditions of heat, excitement and drinking, empties his bladder from four to seven times a day, and should be able to sleep seven or eight hours undisturbed. There should be no difficulty, discomfort or urgency about the act. Regular variations from these habits are the first of all symptoms to appear in several urinary diseases and must be inquired into carefully and regarded with grave suspicion when persistently present.

Hematuria always means something wrong in the urinary tract and when persistent or when recurring intermittently it should lead to careful study as to its source and cause, not because the loss of blood is always dangerous, although it may hasten the end in some conditions, but because it is almost invariably an indication of some serious and possibly curable condition.

It is possible for a patient to have some surgical disorder of the urinary tract in which none of these symptoms appear for months, but under continuous observation something will be found if these organs are kept in mind.

So far as I have been able to look up records, there is only one of these surgical conditions which may not be found at any age. Infants and children have been reported as having movable kidneys, calculi, malignant growths, and in fact all these diseases except prostatic hypertrophy.

In every case there is an uncontrollable contraction of the bladder, due possibly to irritation of the lower ureteral fibers, to a calculus in the ureter or bladder, to a new growth in the bladder, to an enlarging median lobe of the prostate, to an inflamed condition of the urethra nearest the bladder outlet, or else to an incompetent voluntary sphincter, any of which conditions may disturb the normal relation between bladder capacity and contraction.

I have seen examples of all these conditions and doubtless there are others that will produce the same symptom. It is too suggestive to be neglected and must bear an intimate relation to

Incontinence.—Except in the overflow of distended bladders and as it may suggest search for and removal of all irritations wherever found, incontinence of urine has no surgical significance in this paper.

Difficulty in Urination.—This is perhaps as common a symptom as any and results from either mechanical obstruction or from some fault in the nerve supply. It occurs in conscious patients with paralysis of the abdominal muscles and competent sphincter, as well as in those who are in a comatose or delirious condition.

My observation has led me to believe that paralytic and comatose patients are quite as apt to be incontinent as to have retention, unless there is some obstacle which they had previously been able to overcome by voluntary abdominal pressure.

The mechanical obstruction of which we hear most to-day is the hypertrophied prostate, and while unable to discuss it as I should like, I would remind you that it is not a disease of advanced life exclusively. Several cases have been reported in the thirties, and between forty and forty-five the number of men whose prostate begins to produce some discomfort and residual urine is very considerable.

Anuria.—This may occur in the course of certain acute diseases, as a result of some forms of poisoning, after trauma to the urinary tract below the kidney, or to the kidney itself, from vaguely understood reflex disturbances outside the urinary tract, and from any condition which mechanically obstructs the flow of urine into the bladder. The last group of cases is not always easy of separation from the others. Fortunately patients usually go from two to five days before symptoms of uremia appear, and this allows sufficient time, if properly used, for decision and for operative measures if necessary. Absence of urine in the bladder during twelve consecutive hours, if proved by a catheter, may well arouse grave apprehensions, and twenty-four hours is a limit beyond which the responsibility lies very heavily on any single practitioner.

HEMATURIA.

Red blood may show in the urine in amounts recognizable to the naked eye, with or without clots, or in such quantity as only to be recognized by the aid of the microscope. In either case, it may be intermittent in appearance, but in the first case blood is likely to be found on microscopic search long after it has apparently disappeared.

While it may come from any part of the urinary tract and from several causes, persistent or recurring hematuria is so strongly suggestive of a new growth that, next to anuria, it is the gravest single symptom of all.

According to Albarran, hemorrhage was the first symptom in 78 per cent. of 140 malignant bladder tumors and was present at some period in nearly all. According to Israel, 70 per cent. of 66 malignant renal tumors were first indicated by hemorrhage, and 93 per cent. showed it at some period. Deneclara, in 168 cases of tumor of the kidney in the adult, found that hemorrhage was the first symptom in 69 per cent. Even under exceptionally favorable conditions the cause and source of the hemorrrhage may remain in doubt for years.

A patient of mine had hematuria for three years without renal symptoms or palpable tumor. There was no loss of weight or strength and he was particularly active physically. He had a slowly growing prostate with considerable swelling and redness of the median portion, as seen through a cystoscope, which was supposed by one of our most experienced men as well as by myself, to be the source of the hemorrhage. A third surgeon, seeing him six months later, found a distinct renal tumor and a hypernephroma at operation. This experience has taught me never to accept a probable cause of hematuria without ruling out other possible causes.

While hematuria may possibly be due to some harmless condition, its almost constant association with malignant disease and calculi, make it, to my mind, quite as grave, though not so urgent a symptom as anuria of a few hours' duration.

All writers agree that blood in the urine appearing without reference to any physical violence, exertion, or jarring, is very suggestive of new growths. When the hematuria follows such violence, even if slight, they consider it more probably due to the presence of a calculus. In either case it is a hematuria.

If there be also a pyuria, the diagnosis is complicated by an infection which may wholly account for the hematuria or which may be a secondary process grafted on to the original disease.

Continuous or Recurring Discomfort.—This brings us to the most frequent of all urinary conditions—continuous or recurring discomfort rather than pain, often poorly localized, little if any disturbance of function, little if any blood in the urine, but pus in the bladder, urine continuously in varying amounts. The majority of patients with these symptoms can be cared for by any man who will handle a catheter and his solutions in a cleanly way; many will recover if they will wash themselves out by drinking enough water, but the other sort who continue in about the same condition for months, swallowing everything from hexamethylenamine to various nostrums, are the patients who appear later with incurable tuberculosis, or inoperable cancer of bladder, ureter or kidney, with trabeculated and rotten bladders, with kidneys ruined by calculus obstruction, or honeycombed with pus, or transformed into that puzzle of the pathologist—amyloid. These are the cases which arouse regret in the mind of the surgeon, or of the pathologist.

If these symptoms will disappear at all under irrigation and monosyllabic or polysyllabic treatment, they will go within a few weeks at most. If they persist longer, either the infection is not reached by the bladder irrigation or controlled by the chemicals, there is an infection in the deeper tissues, or else the pus is masking some condition like a calculus or a new growth, which is entirely distinct from the infection, though it may be the predisposing cause.

This is the time to study the case by every available method until the condition is understood and proper measures and time for treatment are determined. A patient neglected at this stage may get well from a colon bacillus pyelitis or may pass a small calculus through the natural channels, or possibly make a spontaneous recovery from a tubercular infection, but who can tell which patient will do this and which get steadily worse.

Of pyelitis, Kelley of Baltimore says in substance: "It is of the utmost importance, but is rarely recognized in the earlier stages, or when found is often thought unworthy of attention because not immediately provocative of serious symptoms. The kidney is an organ more necessary than the uterus or Fallopian tubes, but there is a general indifference to mild cases of pyelitis, while the large pus kidneys are noticed. It is important to recognize any grade because the severe cases may result from the mild."

Pyelitis, pyelonephrosis, pyonephrosis, perinephritic abscess, all infective processes, cover one-fifth of all surgical kidney admissions to the two hospitals. If to these we add the cases of tubercular infection which may also show early purulent urine, we take in nearly one-third of the surgical kidneys.

If we follow modern theories and include the calculus cases as caused by an earlier inflammatory condition which might possibly have been recognized, we find that one-half of these surgical kidneys might have been suspected in an early stage from the presence of pus in the urine, and that the patients might possibly have been spared some suffering at least.

Inflammatory processes in the bladder are likely to be recognized earlier because of the alteration in function which nearly always accompanies them and because of the pain which also impresses the patient with the idea that something is wrong.

The inflammatory condition which persists longest without symptom is found in prostatic hypertrophy. Often nothing is noticed by the patient until he suddenly realizes that he has to rise one or more times at night to empty his bladder. This symptom in a man over 40 is always suggestive and characteristic of a bladder with residual urine.

General Symptoms.—Patients with surgical disease of one kidney are apt to sleep on the affected side; varicocele may develop on the same side as a kidney tumor; kidneys with acutely distended pelves and capsules are exquisitely tender, while some hydronephrotic kidneys and very large tumors may be little sensitive. Rectal or vaginal touch may discover tenderness over the lower end of one ureter indicating trouble higher up on that side; median obstruction in the prostate is not always to be felt by the rectum. A tender "Israel's point"—junction of twelfth rib with the outer border of erector spinæ, is valuable in identifying the kidney as a source of vague abdominal pain. The normal kidney, ureter, bladder and prostate are not painful under reasonable pressure.

SUMMARY.

Localized pain, altered function, hematuria, with or without pus—these are the cardinal symptoms of surgical disease in the urinary tract. Tumor, tenderness and residual urine do not require complicated apparatus for their recognition, and their presence or absence can be determined by any physician who will take the trouble to examine his patients properly. These preliminary points are simple, sufficient for a correct diagnosis sometimes, and always trustworthy in indicating the urinary tract as a source of trouble. Nothing in surgery requires more concentrated attention, more accurate observation, or a finer technic, than a complete and correct preoperative diagnosis of the more obscure conditions in the urinary tract which stand between our patients and health.

LATERAL DISPLACEMENT OF TENDON INSERTIONS FOR THE CURE OF STRABISMUS.*

EDWARD JACKSON, M.D.,
DENVER.

The recti muscles act on the eyeball from a common origin. Their normal directions prolonged backward would pass practically to a common point in the outer, lower wall of the optic foramen. Their differences of action depend on differences of insertion. By lateral displacement of its insertion one rectus might be made to take up the function of either of the others. A displacement of not more than 15 mm. up or down, and out, would cause the internus to perform the function of the superior or the inferior rectus.

Some lateral displacement of the insertion of the recti tendons is possible; and any portion of such lateral displacement can bring about a corresponding change of function. Conceive a plane passed through the insertions of the recti muscles roughly perpendicular to the antero-posterior axis of the eyeball, intersecting the sclera in the circumference of a circle. Then the new function of the muscle, produced by the lateral displacement of its insertion, corresponds to the sine of the arc of that displacement.

Let Fig. 1 represent such a circumference with the internal superior, external and inferior recti insertions at A, B, C, D, respectively. If the insertion of the internus be removed from A to E, it will continue to turn the eye inward with a force measured by M O, the cosine of the angle A O E. But it will also tend to turn the eye upward with a force proportioned to M E, the sine of the angle A O E. As the angle A O E is increased, its sine increases, while its cosine diminishes. If the displacement were through 90 degrees, bringing the insertion of the internus to B, the cosine of the angle becoming zero and the sine equal to the radius, the full force of the internus would be exerted in turning the eye up.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The eyeball and the recti muscles are not suspended freely in the orbit, so that neither rectus can have its insertion displaced laterally until it can replace in function one of the other recti muscles. Still, they are each capable of sufficient lateral displacement to give very important practical aid in the correction of strabismus. Each muscle lies embedded in tissue from its origin to its insertion. Its sheath is more or less closely connected with adjoining tissues throughout. Still, the tissues surrounding the muscles are comparatively soft and yielding, and the adhesions of its sheath have little more power to prevent its lateral displacement than to prevent its advancement or retraction. Moreover, the form of a rectus muscle is distinctly favorable to lateral displacement. Starting from a comparatively narrow tendon of origin, it broadens to a comparatively wide (8 to 12 mm.) tendon of insertion; and within the limits of this breadth of insertion it is capable of almost free lateral displacement.

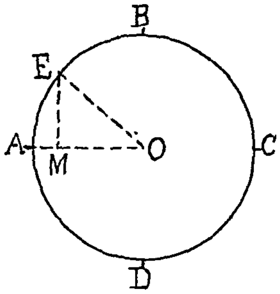

Figure 1.

Let Fig. 2 represent the origin of the rectus muscle and B C its insertion. In its normal condition we may regard the force of the muscle as exerted at the middle point D of the insertion. But if the whole insertion be divided except at the point B, and the tendon of the insertion gathered together so that the force of the muscle will be exerted at that point, the effect will be equivalent to that of a lateral displacement, by half of the width of the tendon of insertion. The form assumed by the muscle will be approximately that shown in Fig. 3.

The alteration of functions of the recti muscles by lateral displacements is favored by the fact that under normal conditions the function of each of the recti muscles varies with the direction in which the eyeball is turned. For instance, with the eye turned strongly inward, the superior and inferior recti come to the assistance of the internus and aid in convergence. With the eye turned strongly outward, they lose all tendency to turn the eye inward and may even aid divergence. Since the superior and inferior recti thus normally become adductors or abductors of the eyeball, it is possible to alter their function by lateral displacement without seriously disturbing muscular co-ordination and control.

The two ways in which I have accomplished lateral displacement of the tendon insertion are partial tenotomy and complete tenotomy, with suture of the tendon to the site of desired insertion. The latter will not be dwelt on here, as I have described[1] it at length in reporting two cases in which lateral displacement of the superior rectus was done for the relief of paresis of the superior oblique.

PARTIAL TENOTOMY.

The division of the tendon begins at one edge of the insertion and extends beyond the middle. To have very much effect, almost the whole breadth of the insertion must be divided. But sufficient tissue should be left to keep the uncut side of the tendon perfectly firm. Any giving of the undivided margin, either at the time of operation or subsequently under inflammatory changes, will diminish the lateral displacement and give somewhat the effect of a setting back of a tendon as by ordinary tenotomy. Therefore, in making this kind of a partial division of the tendon, the whole tendon should be raised on the strabismus hook and drawn on so that the operator will know just how far the firm tissue of the tendon extends.

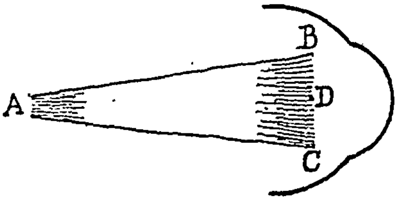

Figure 2.

I have practiced lateral displacement by a partial tenotomy on the superior and inferior recti muscles chiefly for the correction of excess of convergence. Partial tenotomy may be done as the sole operative procedure. For this purpose an incision is made over and parallel to the nasal margin of the superior rectus tendon, 5 or 6 mm. long and commencing 3 mm. back from the cornea. Through this incision a strabismus hook of medium size is to be introduced, passed beneath the tendon, and drawn on until the temporal margin of the tendon is well defined. Small, blunt-pointed tenotomy scissors are then introduced between the strabismus hook and the sclera, with one point behind and the other in front of the tendon, and so much of the insertion as may be desired is divided.

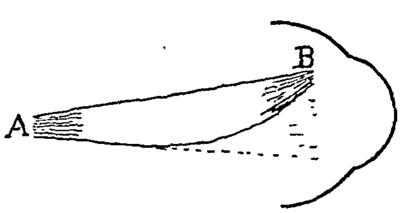

Figure 3.

The lateral displacement produced will be greater if the nasal margin of the tendon is "stripped" for 8 or 10 mm. back from its insertion. "Stripping" is done by passing the point of the strabismus hook backward from the insertion, alternately over and beneath the margin of the tendon; and by using the points of the scissors in a similar manner and snipping any adherent lateral bands.

A similar incision is then to be made along the nasal border of the inferior rectus tendon and the same operation repeated on it. Both the superior and the inferior tendons must be laterally displaced at the same operation; and generally to an equal extent, although for vertical strabismus or hyperphoria the displacement may be made unequal.

---

[1] Ophthalmic Review, March, 1903.

This operation, successfully done, is followed by no diplopia, and by no more reaction than ordinary complete tenotomy. As with other muscle operations, the extent of the hemorrhage and the inconvenience it may cause vary and can not be exactly foreseen. My experience with this form of operation, done alone, is too small to estimate the extent of its influence. But it has proved a satisfactory adjunct to advancement of the opposing muscle.

EXTENDED TENOTOMY.

Lateral displacement of the tendon insertions of the superior and inferior recti in connection with tenotomy of the internus is an effective and reliable operation. The unsatisfactory results obtained by complete tenotomy for high degrees of convergent squint were early noted and commented on. One of the early operators, Phillips, beside dividing the tendon, separated the eyeball from all overlying tissue on both sides of the tendon, and thus undoubtedy encroached on the nasal margin of the superior and inferior tendons. It was said that he obtained satisfactory results in cases that other operators failed to relieve. Velpeau mentioned this practice, with approval based on his own experience. But it seems never to have secured general recognition as an established procedure. Phillips said he sometimes extended his incisions so as to include one-third of the surface of the eyeball. But this would probably involve only a minor part of the width of the superior and inferior tendons; and the lateral displacement thus secured would be but slight. However, the practice was attended by no disastrous results, such as followed repeated tenotomies or the division of the internus too far back.

The operation that I have practiced begins with a complete tenotomy of the internus. Ordinarily for tenotomy of the internus I make the conjunctival incision radiate from the center of the cornea. For this operation, however, I prefer a rather long incision, 10 mm., almost parallel to the corneal margin and slightly in front of the insertion of the internus. Through this the internus is divided at its insertion in the ordinary manner. A strabismus hook of moderate size is then entered at the upper angle of the conjunctival incision, and carried in close contact with the sclera and cornea backward and upward beneath the tendon of the superior rectus. The tendon being well raised on the hook and its temporal margin (that is, its margin of firm tissue) clearly recognized, the scissors are introduced and the nasal one-half to three-fourths of the tendon divided at its insertion. More than one-half of the tendon must be divided to get any decided effect, and the care before mentioned must be exercised to leave at least 2 mm. of the firm portion of the temporal edge of the tendon still attached. Before introducing the strabismus hook the points of the scissors may be used to divide the tissues about the nasal margin of the superior tendon; and before cutting that tendon the hook may be pressed back along the edge of the tendon, as before described, to free it from attachments. This "stripping" of the edge of the tendon may be carried back one-half inch or more from the insertion.

The making of the conjunctival incision approximately parallel to the corneal margin renders it comparatively easy to do conjunctivally the partial tenotomies of the superior and inferior recti from the upper and lower angles of the incision. To prevent falling of the caruncle after such an incision, however, it is well to dissect the overlying tissue rather freely from the tendon of the internus before cutting that tendon; and to complete the operation by bringing together the conjunctival wound by a suture. The after-treatment is similar to that of a simple advancement operation.

It will be noted that this operation produces not simply a lateral displacement of the tendon. As regards the contracted nasal margin of the muscle, it gives the backward displacement of the insertion such as is produced on the muscle as a whole by the ordinary tenotomy. The results to be obtained by this operation may be illustrated by a single case:

Mr. C. P., aged 27, gave the following history: His eyes began to get crossed when he was about 7 years old. At first it was entirely intermittent, but it became more frequent; and when he was 10 or 11 years old it became constant. He was going to school during that time. The strabismus continued slowly to increase until the age of 18 or 20. Since that time he thought there had been no change in it. He had never noticed diplopia.

The amount of squint varied from 80 to 100 centrads (45 to 60 degrees) or fully 10 mm. The inner margin of the cornea was concealed behind the folds at the inner canthus in both eyes at the same time. Either eye was used habitually, the right only to fix objects to the left of the median line, and the left only to fix objects to the right of the median line. The carrying of the object across the median line to the distance of 10 degrees, either way, invariably caused a change of fixation from one eye to the other. Still, by covering the other eye, either could be made to turn out beyond the median line. The vertical movements were fairly executed. There was constant moderate nystagmus. The eye-grounds were good. The correcting lenses and vision obtained with them were: Right eye + 2. ○ + 2.25 cyl. ax. 60° = 4/9 partly. Left eye + 1. ○ + 2.25 cyl. ax. 120° = 4/12 partly.

Under cocain, with the assistance of Dr. E. W. Stevens, I did the operation above described on the left eye, dividing the nasal two-thirds or three-fourths of each tendon (about 7 mm.) at its insertion. This was followed by notable increase in the freedom of outward rotation. The conjunctival opening was closed by two sutures.

At the end of 30 hours all dressings were discontinued. The convergence remaining amounted to 50 centrads (30 degrees). But there was marked increase in the range of movement for both eyes.

At four days the stitches were removed. They had caused no irritation. The convergence now remaining was 35 centrads (20 degrees). There was marked improvement in the fixation of both eyes, there being now quite a field in which either eye could fix, making it a true alternating strabismus.

On the twenty-sixth day it was possible to obtain binocular diplopia, and with prisms of 36 centrads bases out, the Maddox rod showed equilibrium. At this time the patient used the eye that had been tenotomized, almost to the exclusion of the other; although it had vision of only 4/12 partly and the other had vision of 4/9 partly. This was evidently due to the greater ease with which the left eye was moved. When he was required to fix something requiring his best vision he would by movements of the head bring the right eye into use.

The next day the right eye was operated on in a similar manner, dividing the full two-thirds of the tendons of the superior and inferior recti from the nasal side. The conjunctival stitches were removed on the second day, with over 20 centrads (12 degrees) of convergence still remaining. During the succeeding two weeks the convergence gradually lessened, and at the end of that time the eyes were mostly parallel for distant vision, although they still showed excess of convergence for near vision. By this time he was able to fix with either eye, and was beginning to show a preference for the right eye, which had the better vision.

The cure seems permanent, but full binocular vision has not been obtained. Although diplopia is readily excited, it seems to give him no annoyance when the visual axes are allowed to deviate inward during near vision.

At the close of the first operation of this kind it was entered in the case record: "The operation was not difficult and not much more painful than an ordinary free tenotomy. It was less serious than an advancement." This was held true equally of subsequent operations. The ensuing reaction and disturbance have not been greater than after the simplest advancement operations. This case was operated on in August, 1899. Five years later the result remained unchanged. In none of the few cases on which the operation has been done has there been any unfavorable result, either at the time of operation or subsequently.

It might be feared that such extensive division would be followed by protrusion of the eyeball. I have seen quite notable protrusion after what seemed to be a badly performed tenotomy, but nothing of the kind after the operation just described.

In September last I operated on Mrs. H. for convergence of 80 centrads and upward, reducing it to 10 or 15 centrads (6 or 8 degrees) by one operation. This included complete tenotomy of the internus, division of the nasal three-fourths of the superior and inferior recti tendons, and advancement of the externus. She was watched from day to day for protrusion of the eyeball; and neither immediately after the operation nor at any subsequent period was there a perceptible increase in the prominence of the operated eye. In every case the total mobility of the eyes has been increased by operation.

The number of cases in which I have advised and performed these operations is small. But I am certain that they constitute a valuable addition to our operative resources for the treatment of strabismus.

DISCUSSION.

Dr. G. C. Savage, Nashville, Tenn., considered Dr. Jackson incorrect in his statement that, when a muscle is displaced to the line of attachment of another muscle, the former will perform the function of the latter. Suppose the internus is made to take the place of the externus; when the convergence impulse is sent down, the left eye will turn in and the right will sweep out. Suppose, again, that the right externus is made to take the place of the right internus; the neuricity from the fourth conjugate center will cause the left eye to go toward the right and the right eye to go toward the left. The impulse determines which way the eye will turn.

There are two doors to the house of trouble. The first is labeled "a complete tenotomy." The other is marked "displaced attachment when there was no cyclophoria." Just as certain as one makes a marginal tenontomy, when there is not cyclophoria, the patient and the operator, said Dr. Savage, get into the house of trouble. When a muscle is displaced by advancement, unless there is cyclophoria, surgeon and patient get into trouble. When there is a cyclophoria it is a mistake not to do a marginal tenotomy. Dr. Savage said that in 1890 he pointed out the dangers of advancements, the danger of getting the attachment too high or too low and causing a cyclophoria. He said that the operation which Dr. Jackson described should be done in suitable cases, those cases have cyclophoria or cyclotropia. There are curable cases of squint that can not be cured by simple tenotomy; for these cases have cyclotropia. Until they are measured to determine which part of the tendon to divide and which not, the patient will not get well. There can be no question that in some cases marginal tenotomy is indicated and that in others it is not; some cases in which the weaker muscle may be advanced and its attachment displaced, and in others in which, if that is done, the patient is made a thousandfold worse.

Dr. Edward Jackson said that he does comparatively few muscle operations of any kind. The operation described has not been done on patients that possessed binocular vision or who have been capable of developing it. There has been absolutely no trouble from "rotation" of the eye ball. It is possible that this has been avoided by operating on both the superior and inferior muscles at the same time. In the cases alluded to, published in the *Ophthalmic Review*, there was, as part of the paresis of the superior oblique muscle, a distinct tendency to rotation which the operation corrected. Dr. Jackson remarked that the points that he wanted to make were that the internus is not the sole adductor and the externus is not the sole abductor. In cases of high convergent strabismus he believes that the inner portion, the nasal portion of the superior and inferior recti muscles, afford quite as great an obstacle to the proper turning of the eye as the internus itself. He has not only done this operation, but he knows of two instances in which Dr. Stevens of Denver has done it with complete satisfaction. He reported his first case in detail because it has now been six years; and five years after the operation the result was practically the same as shortly after it. He believes that the bad ultimate results from tenotomies, which we still see, are not due to the fact that complete tenotomy is not a proper operation, but to the fact that it is not applied properly, or is applied to cases that should not be subjected to it.

SYMPATHETIC INFLAMMATION FOLLOWING PANOPHTHALMITIS.*

WILLIAM ZENTMAYER, M.D.
PHILADELPHIA.

Until within a comparatively recent period in the history of sympathetic inflammation it had been held that eyes which had been the seat of purulent panophthalmitis did not excite sympathetic inflammation. In 1876, Alt, as a result of original observation and a survey of the literature of the subject, stated that panophthalmitis was among the conditions found in the exciting eye. Notwithstanding this, some authors, among them Fuchs, consider phthisical globes (sequel of panopthalmitis) harmless, and make a distinction between such eyes and atrophied globes (sequel of plastic uveitis).

Knapp states that after panophthalmitis "the eye shrinks, but will remain free from irritation without jeopardizing the integrity of the fellow eye." Treacher Collins says of the inflammation in the exciting eye that it is always of a seroplastic and not of a suppurative type.

Schirmer, in 1900, stated that he had found uveitis purulenta present in only two of twenty-one exciting eyes, and had collected nine instances in 100 exciting eyes. He says that he uses the term "uveitis purulenta" designedly, as the classical picture of panophthalmitis was present only in a minority of the reported cases, whereas the clinical diagnosis had been panophthalmitis. In his own cases the microscopic examination showed that the purulent inflammation was not of the severest type, as the retina and choroid were completely preserved in the posterior segment of the globe and showed changes such as we are accustomed to find in plastic uveitis. He further says that, while he could not assert that sympathetic ophthalmitis can not occur after severe panophthalmitis, it must, in all events, be of extraordinary rarity.

Ruge, as a result of laborious investigations undertaken to determine whether a difference in type exists between exciting and non-exciting idiopathic or traumatic uveitis, asserts the correctness of Schirmer's findings and concludes that true purulent panophthalmitis *never* induces sympathetic ophthalmitis.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

In 1904, Ahlström reported a case in which these conditions were associated and takes issue with both Schirmer and Ruge, as he thinks that in every panophthalmitic eye that is not enucleated within a short time of the beginning of the disease there is practically the same picture that these authors saw, and he believes it to be the expression of the termination of purulent panophthalmitis.

I have succeeded in finding the records of fifteen cases of panophthalmitis followed by sympathetic inflammation. In eight of these there is an anatomic description of the eye. In five there is also a report of the microscopic findings. In three the data are insufficient for a critical consideration.

In the first of Schirmer's cases, an insect had flown into the left eye, causing an inflammation which became progressively worse until, when seen by Schirmer two months from onset, panophthalmitis had developed. About three weeks subsequently the eye was enucleated. Eleven weeks later sympathetic inflammation occurred.

In the second case, the eye became inflamed as a complication of measles. Panophthalmitis followed a perforating ulcer of the cornea. Sympathetic inflammation took place four months later. In both cases the choroid and retina were well preserved in the posterior segment of the ball, whereas the iris and ciliary body were highly disorganized. The changes in the choroid were those of a plastic inflammation. It was greatly thickened and contained nests of mononuclear round cells within the stroma and relatively intact capillary walls.

In Gunn's first case, panophthalmitis occurred on the fourth day after the operation of cataract extraction, and sympathetic inflammation followed ten weeks later. The exciting globe was shrunken and there was a slightly vascular cicatrix corresponding to the operation wound. Above this there was a small, round, fleshy swelling in the conjunctiva. Anatomic examination revealed great thickening of the sclerotic and of the uveal structures. The retina was indistinguishable, and the center of the globe was occupied by tough fibrous tissue, in which was imbedded several calcareous particles. The microscopic description is that of a fibrino-plastic inflammation.

In a second case by Gunn, the operation for cataract extraction, one year previously, was followed by late panophthalmitis. The date of the onset of the sympathetic inflammation was unknown. The result of the cataract operation had been bad at the time. The exciting eye was panophthalmitic, with gaping wound through which the iris protruded. Pathologic examination of the excised eye showed great thickening of choroid and iris. A pea-sized cavity, probably formed by the detached retina, was filled with a red fluid containing shreds of a purulent appearance. There were purulent remnants of the vitreous body.

Three cases of suppurating iridocyclitis following cataract extraction, with sympathetic inflammation as a sequel, are reported by Millis. In but one of these is there a reasonable certainty that there was actual panophthalmitis. Sympathetic inflammation occurred seven weeks after the extraction. There are no pathologic data.

Bickerton's case was one of perforating wound in the ciliary region, followed in three days' time by panophthalmitis. Sympathetic inflammation occurred ninety-seven days after the injury, and there were four distinct attacks. The pathologic notes are that there was a small, shrunken stump about the size of a small marble.

In the case reported by Deutschmann (case of Weiland), sepsis and panophthalmitis followed a mastoid operation. There was phthisis bulbi without previous perforation of the globe. Eight months later sympathetic inflammation developed. The cornea and sclera were greatly and to an equal degree thickened. The choroid was atrophied and the ciliary body thickened. The retina was totally detached. The vitreous was dragged forward into the lenticular fossa. Microscopically the cornea was vascular but intact, and there was round-cell infiltration of the lamella. The anterior chamber contained fibrous exudate, mixed with round cells. Round-cell infiltration of the iris and ciliary body was present. There was atrophy of the choroidal body in various stages of degeneration. The folded lens capsule was attached anteriorly to the iris and ciliary body by an infiltrated fibrous tissue composed of the vitreous. The retina was attached, in part, to the vitreous mass by fibrous bands. The choroid was infiltrated by round cells. *Staphylococcus pyogenes* was present.

Scheffel's case resembled the above case. Following choroiditis metastatica postmeningitiden, the globe became shrunken one half. Scheffel states that, owing to the accepted view that, after panophthalmitis, sympathetic inflammation is scarcely to be feared, enucleation was not performed. Sympathetic ophthalmitis occurred two months from the onset of the inflammation.

In Ahlström's case there was an infected traumatic ulcer of the cornea. This was cauterized and a punctiform paracentesis performed. There resulted an adherent leucoma, possibly of a fistulous type. There was bilateral dacryocystitis, for which the sacs were enucleated. The eye did well for four months, when it became inflamed. When Ahlström again saw it there was a subsiding panophthalmitis, with two scleral perforations. The excised ball measured 18x19 mm. and its form was well retained. The inner coats of the eye were almost completely destroyed. There were remnants of the ciliary body and of the choroid. The latter for a short distance above the nerve head. A granulation polyp extended from the purulent vitreous to the perforation in the sclera, through which it projected. Microscopically the picture was one of a purulent destruction of the intraocular tunics. Numerous colonies of cocci, presumably staphylococci, were found in the vitreous abscess and in the choroid.

In 1876 Alt tabulated the anatomic findings in 110 cases in which sympathetic inflammation or sympathetic irritation had been excited, and in his conclusions states that purulent panophthalmitis was found to be an exciting cause, and further states that, in thirteen instances of panophthalmitis purulenta, iridochoroiditis was induced in the sympathizing eye. From a careful examination of the abstracts given in this exhaustive résumé, and where possible of the original records, it was found that of these thirteen instances in all but two (Justi and Packer) the inflammation was described as either of a plastic or a purulent type, or there were changes present which result from plastic inflammation.

In the oft-cited case of Lawson, the globe was shrunken one-third, the greater part of the cornea was occupied by a cicatrix. T.— =2. Sympathetic ophthalmia followed the wearing of an artificial eye. This was probably the remains of an eye once the seat of a mixed type of inflammation.

In Craig's case there was a history of a panophthalmitis five years previously, following a perforating ulcer of the cornea. The globe was phthisical. Vision in the fellow eye had been failing for one year. There was slight ciliary injection. Total posterior synechia; shallow anterior chamber and T=+1. The nerve was atrophic and showed pathologic cupping. Iridectomy was done. Two weeks later the eye was quiet and tension normal. From the symptoms and behavior of the eye under iridectomy this may be considered a doubtful case of sympathetic inflammation.

My own case is as follows:

M. K., aged 70, was first seen at St. Mary's Hospital on April 1, 1902, when an examination showed in the right eye an immature cataract in an otherwise apparently healthy eye. In the left eye there was an incipient cataract. The fundus showed no gross changes. The patient returned in September, 1904, with a mature cataract. The candle field was good. The patient was frail and poorly nourished. There was neither albumin nor sugar in the urine. The cataract was extracted October 1. An upward section with a small conjunctival flap was made with difficulty, owing to the globe being deep set. The lens could not be made to present and was removed by the wire loop. The eye was examined at the end of twenty-four hours, at which time there was undue corneal haze. On the sixth day the cornea had cleared except for the persistence of a striated keratitis. When again seen by me on the eighth day the cornea wound was infiltrated with pus. The lips of the wound were thoroughly cauterized with the actual cautery, and iced compresses and iodoform were used. These measures having failed to arrest the suppurative process by the end of forty-eight hours, all the involved tissues were again cauterized. Notwithstanding this panophthalmitis followed with only moderate proptosis and edema of the lids. Enucleation was again and again advised but refused, and after an eight week's stay in the hospital she was discharged with a shrunken, tender globe.

December 8 she returned to the hospital, stating that for the past five days the fellow eye had been annoying her, and that the sight had been growing dim. There was a marked uveitis with exudate in the pupillary space and adhesions of the iris to the capsule of the lens along the lower pupillary margin. She absolutely refused to have the shrunken ball removed or to have the inflamed eye treated. She was not seen again for one week's time, when she presented herself at my service at the Wills Eye Hospital, willing this time to submit to enucleation. The sympathizing eye was markedly congested, the pupil small and vision reduced to finger counting. The shrunken globe was at once enucleated and active measures instituted to control the inflammation in the left eye. Inunctions of mercury and salicylate of soda, after the method of Gifford, with milk punches, were employed. After three weeks of this treatment some improvement was noted, but the patient failed rapidly in strength and was very much depressed mentally. Relapses in the condition of the eye occurred and in the early part of January she suddenly became blind. She was removed from the hospital a few days later and died two weeks subsequently.

The pathologic study was made by Dr. Edward A. Shumway, whose report follows:

"The eyeball is in a state of well advanced phthisis bulbi, its antero-posterior diameter (in section) measuring only 16 mm. and its transverse diameter 20 mm. The globe is distorted and sclera thickened, and the cornea flattened. The lens is absent and the entire eyeball is filled with cellular exudate.

"Microscopically: The cornea is almost entirely replaced by connective tissue, which contains many blood vessels and much round cell infiltration. The surface epithelium is thickened and irregular, sending inshots of cells into the tissue beneath, and in places is absent over a considerable area. There has been a perforation at the center, and Descemet's membrane is curled up back of the cornea. There is no trace of the lens except for the capsule, which is imbedded in a thick mass of organizing exudate, which presses up against the posterior surface of the cornea. The iris and ciliary bodies are entirely destroyed and can be recognized only by the clumped masses of pigment with which the cellular mass is infiltrated which fills up the interior of the eyeball, and is being converted into organized tissue. To some extent this mass is composed of pus cells. These are particularly prominent on one side in the neighborhod of the ciliary body, and from here a purulent collection surrounds and infiltrates the processes. Elsewhere and in the position of the choroid, the inflammation has more of a plastic character, the cells being mononuclear in type; with them are many endothelial cells, and in certain localities, especially in the posterior half of the eyeball, a great many giant cells (Fig. 1). In the tissue there is no evidence of caseation and hence the process is not to be considered tubercular. These giant cells have been long known and well described, especially by Krause, Axenfeld, Schirmer and others. The cellular mass representing the choroid is separated from the sclera, as the result of the shrinking of the tissue in the interior of the eyeball, and the space thus left is filled with a moderately cellular exudate which is also being organized, and contains numerous fine capillaries. The retina is almost completely destroyed, only traces of it remaining. The vitreous is occupied also by an exudate which contains comparatively few cells but a large amount of fresh blood. It shows also well advanced organization, fine connective tissue processes running in every direction, accompanying newly formed capillaries. The older blood vessels throughout the eyeball show marked changes; their walls are thickened, the cells of the intima are proliferated, and many of the vessels in the choroid are completely obliterated. The ciliary nerves in the thickened sclera are surrounded by dense mantles of round cells, but outside of the sclera they do not show the condition to as marked a degree. The optic nerve is moderately infiltrated, but the chief excess of cells is in the intervaginal space, especially at their blind extremities within the sclera. Here there is a pronounced proliferation of the endothelial cells, and also many infiltrating round cells.

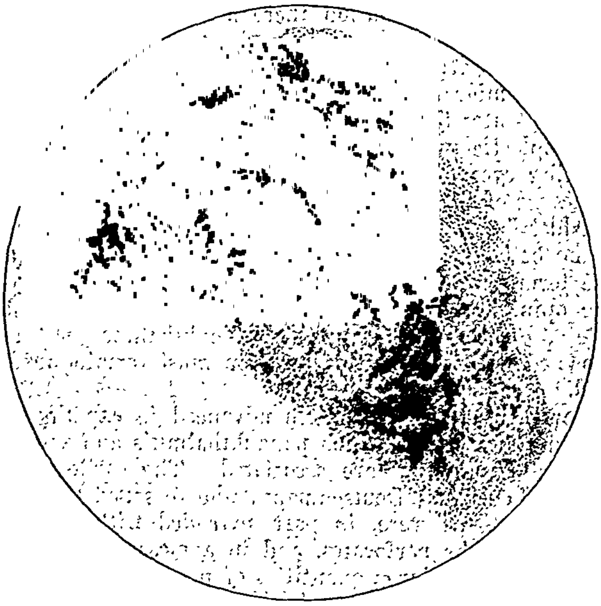

Fig. 1.—Giant cells occurring principally in posterior segment of eyeball.

"The examination, therefore, shows that the contents of the eyeball has been destroyed by a purulent inflammation (panophthalmitis), which has evidently spread from the anterior segment, from the perforated cornea, and has been succeeded by a plastic form of inflammation, with the production of many giant cells, and the proliferation of the endothelial cells of the tissue. This tissue is now going on to the formation of connective tissue, which is causing shrinking and distortion of the eyeball.

"There is a moderate neuritis, but a more marked perineuritis, and an infiltration of the ciliary nerves. This description is very like the usual findings in eyeballs which have been removed on account of sympathetic inflammation, and supports the view of Schirmer, that in cases of panophthalmitis which have caused sympathetic inflammation there is probably a mixed infection and a combination of plastic with the purulent inflammation."

I am indebted to Dr. Harold G. Goldberg, curator and pathologist to Wills Hospital, for the preparation of the specimens for microscopic study.

I believe that in some of these cases, i. e., Gunn's second case and Ahlström's case, where the original insult to the eye had been of the nature recognized as being prone to excite sympathetic inflammation and where the usual period of incubation had elapsed, it may safely be questioned whether the panophthalmitis should be held accountable. The absence of microscopic study in many of these cases makes it impossible to determine whether the cases were true instances of purulent panophthalmitis.

The microscopic findings in Schirmer's cases lead him to believe that in panophthalmitic eyes which excite sympathetic inflammation there is a mixed infection; that, besides the pus exciters, the bacteria of chronic fibrinous uveitis entered, survived, further developed, and then migrated to the other eye.

Ruge states that these cases present the evidence of a fibrinoplastic uveitis analogous to the findings in other exciting eyes, and that this chronic inflammation was the cause of the sympathetic inflammation.

Ahlström is not prepared to accept this explanation, as he believes that these changes are an expression of the termination of a purulent inflammation and is of the opinion that so long as our search for a specific microörganism of sympathetic ophthalmia is not crowned with success this question must remain unsettled.

Several theories have been advanced to explain the extreme rarity with which panophthalmitis and sympathetic inflammation are associated. The earliest was that of Leber and Deutschmann, who reasoned that the microörganisms were, in part, extruded with the pus when the globe perforates, and in a measure rendered harmless by the large quantities of pus. Gifford found in experimentally produced panophthalmitis, blocking of the lymphatics as the result of inflammation, and considered that this offered a mechanical obstruction to the migration of the organisms.

Schirmer's explanation is that it is due to the fact that panophthalmitic eyes contain only the microörganisms of suppuration, and that these are incapable of migration, and that where the mixed infection does occur the exciters of pus, being the more virulent, overcome and destroy the other organisms.

CONCLUSIONS.

1. While the occurrence is one of extreme rarity, eyes that present the clinical picture of panophthalmitis may excite sympathetic inflammation.

2. Such eyes, however, usually present microscopic changes analogous to those found in other exciting eyes.

3. With few exceptions in the cases in literature of sympathetic inflammation following phthisis bulbi, the eyes were of the class described by Fuchs as atrophied eyes.

4. Usually it is, clinically, the mild form of purulent uveitis which excites.

5. It is only after panophthalmitis of a virulent type that the resultant shrunken globe should be considered harmless.

6. Where from the nature of the infection the panophthalmitis has been of a low grade, or where as a result of treatment the inflammation has not assumed a virulent type, the eye should be considered a dangerous one and should be enucleated.

7. That in some cases where the purulent panophthalmitis has been considered the exciting cause the original injury or disease may have been responsible.

8. Whether the histologic findings in most panophthalmitic eyes are to be considered the terminal stage of the inflammation or the evidence of a mixed infection is still undecided, but the evidence points strongly to the correctness of the latter assumption.

9. Several factors contribute to render panophthalmitic eyes innoxious. When the globe perforates many of the microörganisms are extruded along with the pus, those retained within the globe becoming inactive through the enormous pus formation. This active pyogenesis, by blocking the posterior lymph spaces, serves to prevent migration of the toxic agents. Finally, the panophthalmitis may have been excited by organisms probably incapable of inducing sympathetic inflammation, such as staphylococci, streptococci and pneumococci.

DISCUSSION.

Dr. E. V. L. Brown, Chicago, said that Dr. Zentmayer did not make clear the significance of the giant cells; they are not supposed to have any relation to tuberculosis in sympathetic ophthalmia.

Dr. J. Hirschberg, Berlin, said that the giant cells are to be found in almost every clear case in which one eye has been perforated and there is sympathetic ophthalmia in the other. The nature of sympathetic ophthalmia is not known, but if we carefully examine the anatomic condition of the exciting eye we find a great similarity to tuberculosis, though not being tuberculosis; and if we carefully examine the ophthalmoscopic condition of the sympathized eye we find a very close resemblance to the syphilitic appearance, but it is not syphilitic.

Dr. William Zentmayer read Dr. Shumway's conclusions to show that the report speaks of the fact that the giant cells could not have been tuberculous because of other microscopic conditions associated with tuberculosis. As to Professor Hirschberg's remarks on the early signs of sympathetic trouble, Dr. Zentmayer said that they could not be determined in this case because the patient remained away from the hospital until an ophthalmoscopic examination was impossible.

scriptions, the latter's based on sixty-five cases observed during the Crimean War.

Following this a certain amount of bacteriologic research was attempted, but nothing definite was accomplished until Pasteur,[2] in 1877, published his work, in which he described the *vibrion septique* and showed its relation to certain forms of septicemia in animals.

Next, in 1883, Trifaud[3] demonstrated a similar organism in some cases of fulminating gaseous gangrene, and in 1885 Chauveau and Arloing[4] established the identity of this germ with the *vibrion septique* of Pasteur.

Although Pasteur's *vibrion septique* has been shown to have been in all probability an impure culture of the bacillus of malignant edema, the majority of modern French authors still ascribe cases of gas infection to this germ, although A. Ricard[5] admits that other bacteria may cause the same clinical picture.

It remained for an American, William Welch, in 1891, to isolate the now generally accepted cause of gas infection, the *Bacillus aerogenes capsulatus,* or *Bacillus welchii* as it has been named in his honor. In 1892 Welch and Nuttall[6] reported a case in which Welch's bacillus was isolated from the body of a man dying from the rupture of an aortic aneurism.

E. Fraenkel[7] seems to have independently described the same bacillus and demonstrated its causal relation to gaseous septicemia.

In August, 1893, the first American case corresponding to the description of the French authors was reported by Graham, Steward and Baldwin,[8] in which, after an abortion, fatal emphysematous septicemia occurred, and the *Bacillus aerogenes capsulatus* was recovered in pure cultures from the blood after death.

In a later article by Welch and Flexner[9] twenty-three cases of various forms of infection by the gas bacillus were detailed, and since this time a rapidly increasing series of cases have been reported by various observers, quite a number of which have terminated in recovery under appropriate surgical treatment.

Bloodgood[10] gave a résumé of cases reported up to that date, omitting puerperal cases. From fourteen published cases and eight unpublished from Dr. Halsted's service at John's Hopkins he draws valuable conclusions as to diagnosis and treatment. Welch,[11] in a most complete article on morbid conditions caused by the *Bacillus aerogenes capsulatus,* discusses forty-six cases of gaseous cellulitis. Bloodgood[12] adds seven cases to those discussed in 1899.

To this list I am able to add six cases from literature and two from personal experience, making a total of sixty-one cases, not more than three of which can be questioned either as not being cellulitis, or because the bacteriologic findings are not sufficiently accurate.

I present here the cases which include all that I have been able to find in the literature at my command: Mann,[13] 1 case; Welch and Flexner,[9] 6; Martin,[14] 1; Bloodgood,[10] 6; Welch reports 2 cases of his own, unpublished, 1 unpublished of Flexner, and 3 unpublished of Carroll; E. Fraenkel,[7] 4; Passow,[15] 1; Dunham,[16] 5; Ferguson,[17] 1; Erdmann,[18] 1; Le Boutillier,[19] 1; Love and Cary,[20], 1; Norris,[21] 1; Hitschmann and Lindenthal,[22] 5; Thorndike,[23], 2; Muscatello,[24] 3; Guillemot,[25] 1; W. Southey Wright,[26] 1; Gildersleeve,[27] 1; B. F. Curtis,[28] 1; J. B. Roberts,[29] 1; George Heaton,[30] 1; L. M. Loeb,[31] 1; Jacobson,[32] 1; Cole,[33] 1; Gould,[34] 1; Rizzo,[35] 1; Sappington,[36] 2; Mann 1, quoted by Welch and Flexner,[9] p. 20 (not included in their 6).

CASE 1.—Capt. W., aged 71, of Wayzata, Minn., came under my care March 16, 1903, for retention of urine due to stricture aggravated by exposure to cold.

History.—Before reaching Minneapolis, he had been relieved by the suprapubic aspiration of forty ounces of bloody urine. Perineal section was done and bladder drained. At the same time a small region of urinary extravasation around the suprapubic puncture was incised. In spite of this early incision an extensive spreading cellulitis of the abdominal wall was set up, which proved obstinate to the treatment instituted, of free incision and hot antiseptic packs. On the sixth day, a marked extension of the abdominal process toward the right side was noticed, and for the first time crepitation of the swollen tissues was observed. An incision was made five inches beyond the former ones, and a peculiar gelatinous condition of the subcutaneous tissues found, there being also considerable fluid and many bubbles of gas.

Bacteriologic Examination.—Cultures were taken at this time and site, which showed *Bacillus aerogenes capsulatus* in pure culture, while those from the older lesions showed also staphylococci.

Treatment.—Extensive parallel incisions were made through the whole swollen area and about two inches beyond in all directions down to the muscles. This striping was about two inches apart, and reached from the ninth rib above to below the line of the iliac crests below, and extended from the axillary line on the left to the backbone on the right. All these strips were separated as far as possible from underlying tissues, freely irrigated with H_2O_2 isolated by wet gauze strips and the whole covered by hot, wet, sterilized dressings.

Result.—Under this treatment, the septic process made no further progress, the sloughs gradually separated, leaving nothing between the bared muscles and the skin; and within six weeks the patient was practically well.

Remarks.—It may be of interest to note that there was no marked change in the patient's condition synchronous with the onset of the gas infection. His general condition at that time was extremely bad, with low delirium and a running pulse, while his temperature did not vary much from the 100 degree mark. The crepitation of the tissues at a point far distant from the extravasation cellulitis was the only diagnostic point. Apparently the gas infection began some

Case 1.—Capt. W., aged 71, of Wayzata, Minn., came under my care March 16, 1903, for retention of urine due to stricture aggravated by exposure to cold.

History.—Before reaching Minneapolis, he had been relieved by the suprapubic aspiration of forty ounces of bloody urine. Perineal section was done and bladder drained. At the same time a small region of urinary extravasation around the suprapubic puncture was incised. In spite of this early incision an extensive spreading cellulitis of the abdominal wall was set up, which proved obstinate to the treatment instituted, of free incision and hot antiseptic packs. On the sixth day, a marked extension of the abdominal process toward the right side was noticed, and for the first time crepitation of the swollen tissues was observed. An incision was made five inches beyond the former ones, and a peculiar gelatinous condition of the subcutaneous tissues found, there being also considerable fluid and many bubbles of gas.

Bacteriologic Examination.—Cultures were taken at this time and site, which showed *Bacillus aerogenes capsulatus* in pure culture, while those from the older lesions showed also staphylococci.

Treatment.—Extensive parallel incisions were made through the whole swollen area and about two inches beyond in all directions down to the muscles. This striping was about two inches apart, and reached from the ninth rib above to below the line of the iliac crests below, and extended from the axillary line on the left to the backbone on the right. All these strips were separated as far as possible from underlying tissues, freely irrigated with H_2O_2 isolated by wet gauze strips and the whole covered by hot, wet, sterilized dressings.

Result.—Under this treatment, the septic process made no further progress, the sloughs gradually separated, leaving nothing between the bared muscles and the skin; and within six weeks the patient was practically well.

Remarks.—It may be of interest to note that there was no marked change in the patient's condition synchronous with the onset of the gas infection. His general condition at that time was extremely bad, with low delirium and a running pulse, while his temperature did not vary much from the 100 degree mark. The crepitation of the tissues at a point far distant from the extravasation cellulitis was the only diagnostic point. Apparently the gas infection began some

days after the urinary extravasation and operation, as no gas was seen until the eighth day of disease, or the sixth day after the urethrotomy. The seat of gas cellulitis was quite distant from the urinary extravasation, and the gas bacillus was found there in pure culture, although the suprapubic cellulitis was undoubtedly an ordinary pus infection. The process certainly did not begin in the perineal urethrotomy wound, as this remained healthy throughout without swelling or sloughing.

Bacteriologic Report.—Cultures were made by Dr. S. M. White of the University of Minnesota, Pathological Department, with the following results: "Anaërobic cultures yield a short, thick bacillus, often with square ends, usually single, occasionally growing out into short chains, non-motile, retains stains by Gram, and stains by ordinary basic dyes. It does not form spores, at least not under ordinary conditions. It forms a heavy granular deposit in glucose broth within 24 hours, and grows in small round colonies in glucose agar shake preparations. Gas formed in one instance in glucose agar. Inoculated intravenously into rabbits which are then killed after 30 minutes and incubated 24 hours, an abundant formation of gas takes place, especially in the liver. Fifteen c.c. broth culture did not kill rabbits. No other bacteria are present in the cultures from new incisions. From older areas the gas bacillus was found mixed with staphylococci.

Case 2.—Mr. W., Jew, married, aged 27.

History.—While on duty as private watchman he was shot December 11, 1904, at 2 a. m., receiving a pistol wound in the left thigh. He was brought to the City Hospital at once, and the house surgeon thoroughly cleansed the wound and applied an antiseptic dressing. The patient rested well during the night, and when I first saw him on rounds in the morning he presented no disturbance of any sort. The first dressing was, therefore, left in place and the wound was not disturbed until the next morning, about 30 hours after the injury. At that time, he showed a rise of temperature to 100.5, with a pulse about 90, much restlessness and anxiety. He also stated that he had been unable to sleep during the night on account of pain about his wound. He was taken to the dressing room and the wound was examined. There was found a bullet wound about one inch below the center of Poupart's ligament, around which there was some slight swelling and dusky redness. A large sterile bullet probe was introduced and a few bubbles of gas escaped from the deeper part of the wound. He was at once ordered to the operating room, but as another operation was in progress, a delay of about two hours was necessary. During this time some of his friends removed him to a private hospital, where he passed into the hands of another surgeon, who later in the day operated, making simply a counter opening for drainage and removal of the bullet; there was no attempt at free incisions through the infiltrated area. After operation his temperature was 101 degrees, pulse 90, respiration 28, and he complained of thirst, severe pain in his hip and thigh, and was apparently unable to sleep. He was very pale and weak, too weak to be restless. On December 13, his condition became gradually worse. He became weaker, dying on December 15 at 2 a. m., seemingly in a state of profound toxemia.

Appearance of Body.—For an area of four inches around the wound of entrance the skin was brawny red, congested and tense, and from about five inches above Poupart's ligament all along down the leg and to the toes the subcutaneous tissue became emphysematous, gas being distinctly palpable, but there was no discoloration of the skin. From the incisions for drainage came a bloody serous discharge and much gas of a foul cooked blood and hydrogen disulphid odor. Streptococci were found in fresh smears and also an unknown bacillus.

Autopsy.—From the records of the Pathological Laboratory of the University of Minnesota, by the courtesy of Professor F. F. Wesbrook.

No postmortem was permitted, but we were allowed to obtain material for bacteriologic examination. The left leg was considerably swollen and emphysematous throughout, this emphysema extending for a distance of about three inches above Poupart's ligament. There were three openings. The first was situated on the anterior aspect of the limb about one inch below the center of Poupart's ligament, and was somewhat irregular, evidently the wound of entrance. The second was situated immediately over the region of the great trochanter. The third was situated on the outer surface of the thigh about the junction of the middle and lower thirds. The two latter were apparently for drainage. From all three, a serous fluid with bubbles of gas could be expressed. Fluid for bacteriologic examination was taken from three sources: (1) the wound of entrance; (2) the lower drainage opening; (3) an opening made in the anterior surface of the thigh about the center of the middle line.

Bacteriologic Findings.—(Material obtained nine hours after death.) Direct smears gave the following results:

1. From the wound of entrance a mixture of streptococci and a large bacillus, roundish ends, apparently with a capsule was taken.

2. From the lower drainage wound and opening made in anterior surface of thigh a pure culture of a bacillus resembling morphologically that found in wound of entrance was isolated.

Cultures.—Sowings were made into glucose broth, on glucose agar, blood serum and litmus lactose agar. These were grown both aërobically and anaërobically. These grown aërobically gave an apparently pure culture of streptococcus pyogenes from wound of entrance. Inoculations from the other two sources showed no growth. Those grown anaërobically showed a spore-bearing bacillus easily stained with simple anilin dyes and retaining the stain by Gram's. The organisms resemble to a certain extent *B. anthracis*, but are somewhat stouter and are more variable in length. Some appear as diplococci, others are chains of various lengths, as many as fifteen elements being observed in one chain. The ends are roundish, but in the chains they are more or less square. They produce a diffuse cloudiness with a slight sediment in broth. On slant agar, the colonies are difficult to describe, being scarcely visible to the naked eye. Glucose agar is fermented, the amount of gas being apparently great. Litmus lactose agar is also fermented and with an acid reaction. The organism killed a guinea pig in forty-eight hours. Two rabbits, animal experiments Nos 318 and 358, showed apparently no effect. A rabbit, animal experiment No. 357, inoculated intravenously and killed within five minutes, after being placed in incubator for eighteen hours, was greatly distended. Postmortem showed gas bubbles abundant in the subcutaneous tissue and muscles of the belly wall. The same phenomena were observed in the liver, spleen, kidney and heart wall, but were most pronounced in the liver. Smears from each of these organs and from the heart's blood showed the organism above described in great abundance. In smears of the heart's blood, capsules were demonstrable. Inoculations into sugar media with heart's blood gave the same results as those obtained from original material.

Bacteriologic Diagnosis.—*B. aerogenes capsulatus* (Welch).

Quoting largely from Welch and Bloodgood, and adding the eight new cases, the points of interest can be summarized as follows: The sex of the patients shows the usual preponderance of males in all diseases largely dependent on traumatism; 48 males to 11 females, with sex not given in two cases. In over 80 per cent. one of the extremities was the seat of the disease, and in all but seven, traumatism or surgery preceded the onset of the disease. The 61 injuries are itemized thus:

Compound fractures	23
Bullet and shot wounds	7
Infusion of salt solution	3
Hypodermic injections	2
Ligation of artery for aneurism	4
External urethrotomy	3
Submaxillary abscess	2
Traumatic rupture of rectum	1
Appendectomy	1

Prostatic abscess	1
Herniotomy	1
Nephrectomy	1
Severe lacerated wounds	2
Spontaneous gas gangrene	4
Spontaneous general emphysema	2
After erysipelas	1
Unexplained	3

The mortality in the 61 cases was a little over 55 per cent. Of 18 compound fractures 8 patients died and 10 recovered after amputation. Of 7 bullet and shot wounds 4 patients died and 3 recovered with and 2 without amputation. Of 3 patients after external urethrotomy 2 died and 1 recovered. This corresponds closely to the general mortality of the whole 61 cases and excluding several of Welch's patients dying of pus infection and tetanus after apparent recovery from gas infection, the average death rate in surgical cases would seem to be about 50 per cent.

ETIOLOGY.

In regard to the etiology of gas infection, Welch has shown that the bacillus is very widely distributed in nature, being especially common in soil, hospital dust and intestinal contents, hence its more frequent occurrence in compound fractures, dirty wounds and operations about the gut and perineum. Its occurrence after operations on the urinary tract, such as urethrotomy and nephrectomy, must be explained as due to accidental contamination by gut contents as the bacillus has not as yet been found in the urine before death. Welch and Bloodgood, however, both seem to favor the probability of the bacteria being carried to the seat of infection in some cases by the blood, as Gwyn[37] has demonstrated their presence in the blood of the living patient.

According to Welch, it is extremely improbable that clinical gas infection is due to other germs than the *Bacillus aerogenes capsulatus*. The bacillus of malignant edema has been reported as causing fatal infection in man, but without gas production. A few cases have been ascribed to the colon bacillus, as case reported by Rizzo,[35] and to the *Bacillus proteus*; but the reports do not show that either anaërobic methods of culture or the inoculation of animals were attempted, so the proof of diagnosis is insufficient, especially in view of Lanier's work. The latter has demonstrated an aërobic form of the gas bacillus which closely resembles the colon bacillus and might be easily mistaken for it.

Certain German workers have made extensive studies which tend to show that the gas bacillus is at least closely related to the bacillus of butyric acid fermentation, so it is probable that the last word has not been spoken in regard to the bacteriology of this class of diseases.

SYMPTOMATOLOGY.

Not much has been added to the descriptions of the older authors, of whom Maissonneuve and Pirogoff give especially full details. The latter,[38] in 1864, described two varieties of gaseous gangrene: First, cases in which gas forms within forty-eight hours and the tissues become gangrenous and melt away without local inflammatory reaction, while the patient becomes early collapsed, anxious, sweating and dies within a few days; and, second, cases in which the local reaction is marked, the course of the disease slower, and in which there is marked fever and the other ordinary symptoms of severe infection. The symptoms noted in the cases listed above have been quite varied and, on the whole, have not been striking, the one constant and diagnostic sign having been the presence of gas in the tissues or in the wound secretions, occurring from the eighth hour to the sixth day. Other symptoms noted have been rarely a chill, regularly a fever ranging from 100 to 104 degrees in the different cases, rapid running pulse, delirium in many cases; locally gas in the tissues surrounding the point of entrance, gas in wound secretions, fetid or stinking odor to discharge and incised tissues, frothy, brownish discharge of horrible odor, dusky redness of the skin followed in some cases by the ordinary color changes of gangrene; general emphysema of extensive areas, sometimes of whole body, explosive escape of gas from tissues when incised, and immense production of gas in all parts of the cadaver after death.

There seems to be much difference of opinion as to whether pure infection by the gas bacillus is more malignant than a mixed infection. Muscatello[24] and Gangitano believe that the mixed infections are the most virulent, and even claim that the gas bacillus is unable to exert any pathologic action on healthy tissues; while Hitschmann and Lindenthal take exactly the opposite view, stating that the pure infections are most virulent; and Welch, while admitting extreme virulence in certain cases of mixed as well as in pure infections, positively contradicts, from experimental experience, the statement that the gas bacillus can not attack healthy tissues. A study of some of the recent cases would suggest that, like tetanus, the relative virulence of this disease in any given case may be indicated by its early development, that is, that cases developing gas symptoms slowly should give the better prognosis.

DIAGNOSIS.

The one diagnostic sign is the presence of gas in the tissues and the presence of the bacillus in smear preparations from the wound, in fact, the latter should be given precedence, as one or two observations establish the fact that this germ may live for some time in a wound without producing gas.

All suspected wounds, therefore, should be subjected to this amount at least of bacteriologic study.

TREATMENT.

All contaminated wounds should be thoroughly cleansed and disinfected, best by carbolic acid, followed by alcohol; although this did not prevent gas infection in one case reported by Bloodgood. As soon as diagnosis is made, by microscope or clinically, the seat of infection should be laid widely open by multiple incisions, and then treated by continuous bath or by irrigation, hydrogen peroxid and wet dressings. When the lesion is confined to an extremity, the consensus of opinion seems to favor early amputation, although the results of conservative treatment seem to indicate that many limbs may be saved by its adoption. The recovery in my case of gas cellulitis in a not robust man of 71, the treatment being merely the very thorough carrying out of the ordinary treatment of any diffuse cellulitis, would suggest that the rather difficult treatment by continuous bath advocated by Blodgood may be dispensed with in some cases. How much the use of H_2O_2 can prevent the growth of an anaërobic bacterium is a matter for speculation; theoretically, it would be indicated locally in this disease, as in tetanus.

CONCLUSIONS.

1. Gas bacillus infection, while not a common disease, demands the attention of all surgeons because, while regularly fatal when untreated, its early diagnosis is

---

[38] Pirogoff: Grundzuege de allgem. Kriegschirurgie, p. 867-1006, Leipzig.

easy and its successful treatment requires only the prompt and thorough application of well-established surgical principles.

2. Either removal of entire disease by amputation or thorough exposure of its site to air and drainage seem the essentials to be attained.

3. Free incisions, the continuous bath, or irrigation and wet dressings, have afforded the best results, and theoretically hydrogen peroxid is indicated.

IMMUNITY.

CHAPTER XXII (Concluded).

TYPHOID FEVER.

Proliferation of Endothelial Cells.

Mallory has given a histologic explanation of certain gross and microscopic changes which characterize typhoid fever, the essential feature of which is a massive endothelial proliferation in the lymphoid organs (Peyer's patches, solitary follicles, mesenteric lymph glands, spleen and bone marrow). It is thought that this process explains in part the enlargement of the lymphoid organs. The cells are phagocytic, and especially in the lymphoid tissue of the intestines and in the mesenteric lymph glands, englobe and destroy the lymphoid cells on a large scale. A similar proliferation of the endothelium of the perivascular lymph spaces and vessels occurs. The proliferated masses undergo necroses, the lymph vessels become occluded and the process, accompanied by fibrin formation, extends to adjacent blood vessels, causing thrombosis of the latter. The death and sloughing of the lymphoid patches is the direct result of this thrombosis, the process being aided by mixed infection with the intestinal bacteria.

Endothelial proliferation in the spleen and bone marrow is of a similar order, and in these organs the cells show their phagocytic properties by ingesting large numbers of erythrocytes. Emboli are formed in the hepatic lobules by the endothelial cells, which are carried from the spleen to the liver through to the portal circulation, a process which results in the small islands of necrosis (focal necrosis) so often found in typhoid livers (Mallory.) It seems probable that the endothelial proliferation which has been described is due to the rather mild but prolonged action of the dissolved toxic constituents of the typhoid bacillus; the condition is that of an inflammatory hyperplasia. The greatest changes take place in the organs (lymphoid) which contain the bacilli most constantly and in the greatest numbers. It is here that the toxic substance may be present in greatest concentration, as a consequence of the continual solution of the organisms. It has been suggested that the hypoleucocytosis of typhoid fever is due to the destruction of the lymphocytes in the lymphoid organs by the endothelial phagocytes.

Granular and fatty degenerations of the parenchymatous organs occur, but these changes are common to many infectious diseases, the mechanism by which they are produced being unknown.

Mixed Infections.

The conditions in the intestinal tract would seem to favor mixed infections, especially by the colon bacillus and streptococcus, and the primary infection probably decreases the resistance to secondary invasion. The rôle of the colon bacillus in typhoid fever is perhaps not definitely established, although it has been found in the circulation, in abscesses, and in the urine in cases of cystitis accompanying the disease. The typhoid and colon bacilli grow well together. A mixed general infection with the streptococcus causes a grave septic condition characterized by an irregular temperature curve. This condition may be discovered by blood cultures. It is thought that the streptococcus does not increase the toxicity of the typhoid bacillus, the result being rather a summation of the intoxication of the two infections. Post-typhoidal suppurations are often due to the streptococcus and in many of the metastatic complications (parotitis, pleurisy, peritonitis, meningitis, otitis media) streptococci and staphylococci have been found. Pneumococcus pneumonia not infrequently complicates typhoid fever. A combined infection of typhoid and malaria is said to occur in the tropics; the complication is grave. Typhoid and diphtheria may occur together, and typhoid may be superimposed on acute tuberculosis.

Immunity and Susceptibility.

The period of greatest susceptibility to typhoid is found from the fifteenth to the twenty-fifth years. The resistance of infants and children is not satisfactorily explained. A certain amount of resistance inherited from the mother may persist for some years after birth. It is known that antibodies may pass from the mother to the fetus through the placenta. In very early life the tissues may respond more energetically to incipient infection by the rapid formation of typhoid antibodies, or the phagocytic cells may be more active. The conditions which render older people less susceptible are no better understood. A loss of suitable receptors may have occurred so that the toxic constituents of the bacilli find no anchorage in the body, or the affinity between the receptors and the toxic constituents may have become less. The individual during the course of years may have been gradually immunized by the entrance of nonpathogenic quantities of the bacilli into the circulation. That resistance to typhoid infection is decreased by low nutrition and overwork is a long-known fact.

Natural and Acquired Immunity.

Natural immunity, to a certain degree, is dependent on the hydrochloric acid content of the gastric juice, and it is reasonable to believe that suppression or an insufficient amount of hydrochloric acid may favor the passage of living bacilli to the intestines. The typhoid bacillus is more resistant to the gastric secretion than the vibrio of cholera. Normal human serum is rather strongly bactericidal for the typhoid bacillus. Metchnikoff ascribes natural immunity to the action of the microphages.

The immunity which follows an attack of typhoid fever is generally of long duration, but second attacks occur with some frequency. It has been noted that limited communities which have experienced an epidemic may remain relatively free from the disease over a period of some years, although neighboring districts are attacked. All the susceptible persons having had the disease, a state of temporary regional immunity is created. Acquired immunity of this type is characterized by the appearance of bactericidal amboceptors, agglutinins and typhoid precipitins in the serum of the individual. It is commonly believed that recovery is due to the increase of the bactericidal power of the body fluids, which becomes most marked during the later period of the disease or during convalescence. It seems certain, however, that the new resistance persists beyond the time when the bactericidal power of the serum has returned to normal, which may take place in from one to several years. The bactericidal power sinks rapidly during and following convalescence. However, the general principle is well established that, although the antibodies may have disappeared entirely, they are formed anew much more readily as a consequence of an old infection. This phenomenon was demonstrated in one instance by Neisser and Shiga in relation to typhoid. The tissue cells have, so to say, been trained, and are stimulated by a few micro-organisms to produce such a quantity of bactericidal amboceptors, that the incipient infection is overcome. It is, of course, understood that the amboceptors require the aid of complement in killing the micro-organisms. A second attack of typhoid fever usually is mild.

Metchnikeff does not deny that the amboceptors (fixators) play an important part in acquired immunity, but claims that the new resistance depends chiefly on an increase in the phagocytic power of the microphages (polymorphnuclear leucocytes). This is not clear from the clinical standpoint because of the hypoleucocytosis which is somewhat characteristic of typhoid—a hypoleucocytosis caused chiefly by a disappearance of the microphages. It has been suggested that our conclusions as to hypoleucocytosis are based on examination of the peripheral blood, whereas the mesenteric vessels may show hyperleucocytosis. Mallory, however, found a striking absence of microphages even in the intestinal vessels. Concerning a theory that the hyperplasia of the lymphoid organs serves as a substitute for the hyperleucocytosis, we may recall the findings of Mallory that this hyperplasia is chiefly one of endothelial cells. The importance of these endothelial cells for the destruction of typhoid bacilli needs further investigation.

Prophylaxis.

Prophylaxis should begin with the thorough disinfection of the stools and urine of typhoid patients, and should continue until they no longer contain typhoid bacilli. Strictly speaking, it is not in conformity with good hygiene to discharge a patient until bacteriologic examination of stools and urine show them to be free from the organisms. It would be difficult to carry out this rigid precaution under all conditions of practice, but at all events the stools and urine may be disinfected for a reasonable period, say throughout convalescence. There is no sufficient reason for the neglect of the bacteriologic examination in hospital practice. There is a growing sentiment that typhoid patients in hospitals should be isolated in wards or rooms in which there is a fixed routine for the disposal of infectious materials—urine stools and sputum. Soiled linen, the bath water of typhoid patients, the remnants of food and drink, and the eating utensils should be disinfected before removal from the room. Nurses or attendants should not eat or drink in typhoid rooms.

Hexamethylenamine.

The value of hexamethylenamine in causing the disappearance of bacilli from the urine is now well known, and the advisability of using the drug as a routine measure for public safety is worthy of consideration. The room should be kept free from flies and eventually it should be disinfected, preferably by formalin. During an epidemic, in case the water supply of a community is susceptible to contamination, all water used for drinking, washing of vegetables and eating utensils should be boiled, and that used for general cleaning may be otherwise disinfected. The possibility of dust infection of a house should not be disregarded.

Vaccination.

There are two methods of specific prophylaxis against typhoid: 1, The injection of antityphoid immune serum; 2, preventive inoculation with killed cultures of the bacilli. Antityphoid serum confers a fairly strong and immediate immunity which, however, is of short duration, because of the rapid elimination of the serum. Its use as a general preventive, therefore, is not advocated.

Wright's Method and Results.

Wright has been the most influential factor in showing the utility of protective inoculations against typhoid. His first experimental work was published in 1896. Since that time the inoculations have been carried on extensively in British regiments in India and South Africa. In the statistics which have been collected the occurrence of typhoid among the individuals inoculated was one-half that among the uninoculated. The inoculations reduced the mortality of the disease by one-half. The protection, so far as known, lasts for two or more years, although in some instances infection has occurred in from three to six months after vaccination.

The Vaccine.

The methods of preparation of the vaccine are elaborate in order to insure sterility and standardization. Cultures of the bacillus are grown in nutrient broth for from twenty-four to forty-eight hours, and then sterilized at 60 C. The contents of several flasks are mixed in order to obtain a uniform distribution of organisms, and standardization is then accomplished by a convenient method of estimating the number of bacilli in a cubic centimeter of the vaccine. The purity of the vaccine is insured by bacteriologic tests, and for preservation carbolic acid or lysol is added.

Effects.

Wright has abandoned his original method of giving a single injection and now recommends two moderate doses, which are given from eight to fourteen days apart. The first dose includes a quantity of vaccine which contains from 750,000,000 to 1,000,000,000 of bacilli, the second 1,500,000,000 to 2,000,000,000. Wright finds that "the inoculation of these quanta induces an ample elaboration of antitropic substances (antibodies) without producing any severe constitutional reaction." We need not here enter into a consideration of Wright's nomenclature. The inoculations increase the bactericidal and agglutinating powers of the serum; it is concluded that an increased resistance to typhoid intoxication is established because the second injection causes milder symptoms than the first and the phagocytic powers of the leucocytes is raised, because of an increase in the "opsonic antitropins" (Chapter XVI). The curve of the antibodies is like that obtained in general by active immunization with bacteria, toxins or other substances. Immediately following the inoculation there is a decrease even of the normal antibodies in the individual's serum. This "negative phase" lasts for from one to several days and corresponds to a period of increased susceptibility. It is quickly followed by a positive phase in which the antibodies and correspondingly the resistance increase rapidly. When very small doses are administered the positive phase may be recognized after twenty-four hours (Wright). Large doses cause a prolonged negative phase and are to be avoided.

Local Reactions.

General Reaction.

Following injection, "the local symptoms first make themselves felt after an interval of two or three hours. The effects then seen are the development of a red blush and more or less serous exudation at the site of inoculation, followed by some lymphangitis along the lymphatics which lead, according as the vaccine has been inoculated above or below the middle line of the trunk, in the direction of the glands of the axillæ or of the groin. . . . Even severe inflammation has never led on to suppuration." The exudate is somewhat hemorrhagic, and the pain moderate to severe, but not of long duration. Pain is relieved by hot application or inunction with a carbolic acid ointment which contains ergot. With the technic as recommended at present, "the constitutional symptoms are limited to some headache and to two or three hours of real malaise. . . . The next day his temperature comes down to normal, and he feels comparatively well except in respect to pain at the seat of inoculation."

Conditions for Vaccination.

The statistics warrant the adoption of antityphoid inoculation or vaccination under certain conditions. Its utility in the army has been demonstrated, and probably will be carried out in future campaigns among educated nations. Typhoid never has been a world pest, hence the occasion for universal vaccination does not exist, but in the presence of epidemic so frequently seen in American cities it will be impossible to avoid the consideration of vaccination as a means of protecting the uninfected. The question may be worthy of consideration also in those cities in which typhoid is so extensive as to be called endemic. The procedure is absolutely safe and the results speak for a high grade of effectiveness.

Mixed Active and Passive Immunizations.

It has been suggested that the "negative phase" described above is a source of danger in the presence of an epidemic. The phase is of so short duration, however, that the danger is minimal. It seems probable that the practice of mixed active and passive immunization would eliminate it entirely. This is accomplished by the combined injection of antityphoid serum and vaccine. The serum assures a positive phase from the start, and before this has subsided, that induced by the vaccine is established. When specific serum is mixed with the vaccine the local action is said to be less severe.

The products of autodigestion of typhoid cultures have been suggested as suitable vaccine (Neisser and Shiga). The local reaction is said to be mild, and the body reacts by the formation of bactericidal amboceptors and agglutinins.

Therapy.
Serum

Bactericidal serums obtained by the immunization of horses with typhoid bacilli have not shown distinct curative properties. This subject was discussed in its theoretical aspects in Chapter XVIII. Chantemesse immunizes horses with a typhoid "toxin" which is prepared by growing the organism in a liquid culture which contains an emulsion of splenic tissue. One cubic centimeter of this toxin will kill a guinea-pig, a dose which in comparison with other bacterial toxins is very weak. Chantemesse has used his antitoxic serum in the treatment in more than 500 cases, reporting a mortality of about 6 per cent., whereas that among untreated patients was from 10 per cent. to 12 per cent. Although these figures indicate some value for the serum it has had little trial outside of France.

McFadyan and Rowland immunize horses with extracts of typhoid bacilli, which have been ground up while they were kept in a brittle state by the temperature of liquid air. Although antitoxic and bactericidal properties are claimed for the serum, there is no conclusive evidence that it differs from a bactericidal serum prepared in the ordinary way.

Preparation of Jez.

Jez produces a high degree of immunity in rabbits by artificial immunization with the typhoid bacillus, then prepares an extract from the spleen, bone marrow, brain, etc., of the immunized animals. The extract is administered by mouth. Jez justifies this method, from the fact that the lymphoid organs have been shown to form typhoid antibodies (Wasserman). From the clinic of Eichorst and some others favorable reports concerning the remedy have been published. It has had no extensive use. The preparation is made by the Serum Institute of Berne (Switzerland) and is expensive.

The suggestion made by Fraenkel, that typhoid patients be treated by subcutaneous injections of small quantities of killed typhoid bacilli in order to hasten the formation of antibodies has been kept alive through the "typhoin" of Petruschky, but is yet without much practical trial.

Agglutination.

The principles and technic of the agglutination test were described in Chapters X and XI. It is sufficiently well known at the present time that the test is a strong corroborative diagnostic sign of typhoid fever, to which there are, however, certain limitations and sources of error. The serum commonly becomes agglutinative on from the seventh to the tenth day, rarely as early as the second or third, and as late as from the twentieth to the fortieth day. The power is highest during convalescence, when it may agglutinate in dilutions as high as from 1 to 5,000 or higher, and from that time sinks gradually. An agglutinating power of from 1 to 160 has often been found at eight months, and of from 1 to 50 after from seven and one-half to eleven years; but the latter duration is not the rule. In performing the test a serum dilution of not less than 1 to 40, or 1 to 50 should be observed as previously set forth.

The following points are to be borne in mind: Typhoid fever occasionally runs its course without the formation of agglutinins; the reaction may mysteriously be absent one day to recur a few days later, from which the importance of repeated tests becomes manifest in case a first test was negative; rather high agglutinating power for the typhoid bacillus occasionally develops in other infections, as pneumonia, meningitis, icterus, Weil's disease, etc.; the possibility of group agglutination, for the positive elimination of which control tests with related organisms may be demanded.

In case negative results are obtained in a suspicious case the reactions should then be tried with the paratyphoid bacilli.

The test of the bactericidal powers of the serum has been recommended as a substitute for the agglutination reaction, but the technic is so much more complicated that the method will probably not come into general use.

For diagnosis previous to the formation of agglutinins blood cultures should be made as described in a preceding paragraph.

Clinical Reports

INTESTINAL INDIGESTION IN AN INFANT FROM HAM RIND.

BLANCH N. EPLER, M.D.
KALAMAZOO, MICH.

Patient.—A child, aged 2 years, a patient of Dr. Della Pierce, had complained of vomiting, abdominal pains and diarrhea for two days.

History.—There was a history of an intestinal indigestion and slight fever of several days' duration. The mother stated that during this time the child passed large pieces of "curd" in the stools.

Course.—The symptoms abated with treatment, and several days later the child passed what the mother called a long, green worm. Recovery was rapid. The so-called worm certainly resembled one on gross inspection. It measured 8 inches and was flat, one side presenting a white curd-like appearance; the other a dull, green, slimy appearance. On careful examination, aided by the microscope and KOH, this substance proved to be the rind of ham or bacon, only slightly attacked by the digestive juices. This is a good example of what is to be expected in babies who are allowed to eat everything.

A CASE OF HYDROCEPHALUS AND ACRANIA.

A. E. ENGZELIUS, M.D.
DENVER, COLO.

The extreme rarity of the occurrence should justify the report of the following case of acrania:

History of Mother.—The mother, Mrs. H. G., aged 23, primipara, has never in her life been sick; she also enjoyed perfect health during the entire term of pregnancy. Delivery occurred on July 20, 1905, about a week later than expected. Fetal movements for the last week had been very feeble, if noticeable at all. On examination the day before labor, fetal heart sounds could not be heard, and palpation of the abdomen failed to elicit fetal movements. The patient, however, was in excellent health.

Labor.—Labor pains set in abruptly and were almost from the start continuous or with very brief intermissions. About three hours after beginning of labor the vagina was found to be filled by a "bag of waters" of unusually large size, through which the presenting part could not be palpated. Puncture of the bag effected during the height of a uterine contraction was followed by a discharge of a somewhat soft and anemic brain substance in considerable amount. This was followed by a very forcible expulsion of about a pint of serum. (The explosion was so forceful as to cause the liquid to spurt over my head and on to the wall behind me, a distance of several feet.) The fetus presented in L. O. A. position.

Description of Fetus.—The body and the face were perfectly developed. The anterior portion of the scalp was normal and thinly covered with hair. Posteriorly, from the level of the *foramen magnum* and continuous with the integument of the neck to the vertex of the skull, there extended, instead of integument, a thin, smooth, translucid and elastic membrane resembling a cyst sac. The occipital bone, both parietal bones and all of the vertical portion of the frontal bone, save an edge about three-eighths of an inch high, were lacking. In other words, the skull cap was entirely absent. The base of the skull was perfectly developed. An accumulation of serum had evidently occurred in the occipital region, behind the brain, and was covered in by the membrane, which, in this situation, was found to have taken the place of normal scalp tissue.

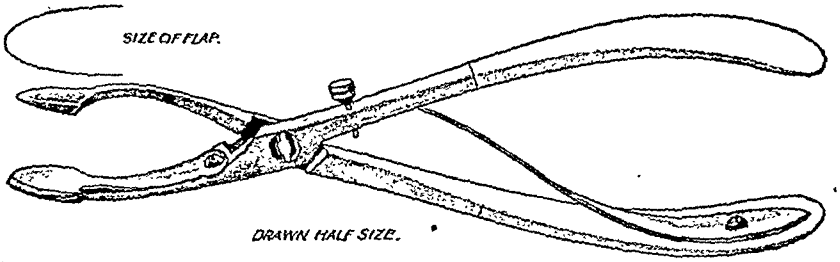
Remarks.—The etiology of this malformation is obscure. Delafield and Prudden[1] state it as probable that the accumulation of fluid is secondary to a primary partial anencephalia. Ziegler[2] quotes on the subject various and from each other widely differing opinions. By some acrania is regarded as due to an abnormal accumulation of fluid in the cerebral vesicles occurring before the fourth fetal month. Others oppose this view and believe the condition to be caused by a pressure from without exerted by the cephalic cap of the amnion, lying snugly against the cephalic bend and thus hindering the development of the cranium. Still another opinion looks for the cause in an abnormally sharp curvature of the body of the embryo, occurring where the cephalic end of the embryo has elongated abnormally, or the cephalic envelope has lagged behind in development. This sharp curvature would prevent the change of the medullary plate into the neural canal or cause the already formed canal to be destroyed. Ziegler remarks that many and various causes might very likely be in operation, and that in some instances the malformation must probably be ascribed to a primary agenesia already determined in the germ.

New Instrument

A NEW SEPTOTOME.*

WALTER A. WELLS, M.D.
Throat and Ear Surgeon, Garfield Hospital.
WASHINGTON, D. C.

This instrument is designed to be used as a substitute for the knife or scissors in cases of uncomplicated deviation of the cartilaginous septum. It cuts out of the cartilaginous portion of the septum a more or less tongue-shaped flap, and it accomplishes with a single incision at least as much as is done in the Asch operation with two separate incisions. Thus is overcome the necessity of removing one set of scissors to substitute another, which may prove a serious drawback in case *one is operating* on a nervous patient under a local anesthetic.



In the Asch operation, the result of the incisions is to create four small, triangular segments with their points in apposition, which means that we have four possible points of sloughing. With the septotome but a single flap is cut, and that having what many rhinologists consider the ideal shape of the flap for this operation; the chances for sloughing, therefore, ought to be decidedly lessened.

By means of a screw, the tongue-shaped flap may be shortened to any desired length; and the instrument is so constructed that the flap, when cut, is bent well to the other side, thus converting the two stages of the Asch operation into one. Moreover, I think a decided advantage is gained over the Asch instrument as regards the introduction of my septotome. There is no sharp point to become engaged in the tissues, as it is being introduced. It has a large and a small jaw, the former for the free side and the latter for the side obstructed. Even though one side of the nose be completely obstructed, the shape and size of the smaller jaw is such that it may be wedged in without any laceration of the tissues.

The object of the flat band of steel, which is attached to the larger jaw of the instrument, is that it will act as a spring and force back into the median line the flap which has been cut out of the septum, a very important provision to prevent its being caught by the instrument as it is being withdrawn.

SATURDAY, AUGUST 19, 1905.

MEDICAL EDUCATION IN THE UNITED STATES.

The present issue of The Journal contains statistics regarding medical education in the United States for the year ending June 30, 1905. The data published herein were obtained directly from the college authorities, from the annual announcements, and from other sources, and especial care has been taken to insure correctness in every instance. We have had the co-operation of practically all the colleges in this work, and we take this opportunity of extending our thanks to those who assisted us in gathering the statistics.

A careful study of the tables will show that medical education has undergone many changes during the past year. The standards of preparation of study and of graduation have been raised considerably, showing that there is a disposition on the part of all concerned to elevate the standard of the profession by bringing into it men and women who are better prepared to practice medicine, and who will be a credit to the profession in every way. There has been a distinct gain in the entrance requirements during the past two or three years. This change for the better is due, in part, to a few individual colleges, but largely it is the result of concerted action on the part of several organizations which have it in their power to promulgate and enforce rules and regulations for the government of colleges. The state examining boards, in particular, have exercised a most wholesome influence by raising the requirements and by taking an active part in the regulation of preliminary or preparatory education.

Number of Medical Students.—The total number medical students (matriculants) in the United S for the year ending June 30, 1905, was 26,147, crease of 1,995 below the year 1904. Of this nu 24,119 were in attendance at the regular schools, 1 at the homeopathic, 578 at the eclectic, 114 at physiomedical, and 232 at the nondescript (unclas able) school. The attendance at the regular schc shows a slight increase—457—over that of last ye and a decrease—801—below 1903, and also a decrea —759—below 1902. In the homeopathic school there was a decrease of 205 below the attendance of 1904, 394 below 1903. In fact, the attendance at the homeopathic schools has been diminishing steadily since 1900. It was less last year than it has ever been since 1880. Up to the present year, the eclectic schools showed an increase in attendance since 1900. This year, however, the attendance fell to 578, 436 less than for 1904, and the lowest attendance since 1880. The attendance at the physiomedical schools has also fallen off a trifle. In 1904 the attendance at these three schools was 129. In 1905 it was 114.

Table of Medical College Attendance.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med and Nondescript.	Total.
1880......	9,776	1,220	830	....	11,826
1890......	13,521	1,164	719	...	15,404
1900......	22,710	1,909	552	...	25,171
1901......	23,846	1,683	664	224	26,417
1902......	24,878	1,617	765	241	27,501
1903......	24,930	1,498	848	339	27,615
1904......	23,662	1,309	1,014	357	28,142
1905......	24,119	1,104	578	346	26,147

These figures tend to show that the attendance at the regular schools is increasing at the expense of that at the sectarian schools. It is evident that the raising of the entrance requirements has been a factor in the lessening of the number of matriculants.

Graduates.—The total number of graduates for the year ending June 30, 1905, was 5,606, a decrease of 141 below the preceding year and 92 below the year 1903. The lowest number of graduates since 1900 was 4,999, in 1902; the highest number was 5,747, in 1904. For the year just closed the percentage of graduates to matriculants was 21.4. For 1904 it was 30.3; for 1903 it was 22.8. The decrease in the number of graduates from the regular colleges in 1905 was 64; from the homeopathic colleges, 95. The number of graduates from the eclectic colleges is 7 greater than it was last year, and 9 in the case of the unclassified college. The graduates of 1905 from the homeopathic colleges have been fewer in number than in any year since 1880. The electic schools, on the other hand, graduated more students in 1905 than in any year since 1890.

Table of Medical College Graduates.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880......	2,673	380	188	..	3,241
1890......	3,853	[illegible]	221	..	4,454
1900......	4,715	[illegible]	86	..	5,214
1901......	4,879	[illegible]	148	..	5,444
1902......	4,498	[illegible]	[illegible]	27	4,999
1903......	5,088	[illegible]	[illegible]	41	5,698
1904......	5,190	[illegible]	[illegible]	40	5,747
1905......	5,126	[illegible]	[illegible]	51	5,606

Women in M [illegible] year 1,073 women were enga [illegible] 1 per cent [illegible] total [illegible] and 219 [illegible] per [illegible] th [illegible] be for some time, but was included in our last year's statistics as an active college. Of the total number of colleges, 126 are regular, 18 homeopathic, 9 eclectic, 3 physiomedical, and 1 unclassified. During the year 2 homeopathic colleges united, and 1 eclectic college changed its faith and is now teaching regular medicine. Six of the regular colleges listed in our tables did not confer degrees, teaching only the first and second years of the medical course. Three colleges (two regular and one homeopathic) are exclusively for women; 63 for men; 91 are coeducational (66 regular, 13 homeopathic, 8 eclectic, 3 physiomedical, and 1 unclassified college). There are five schools to which only colored students are admitted, two less than last year, one having become extinct and the other now admitting both white and colored students. Three schools operate under the continuous course system, the year being divided into quarters, and the student being allowed to attend only a specified number of quarters or semesters in each calendar year. These three schools are located in Chicago. Sixty-eight regular colleges, 4 homeopathic and 1 eclectic college has a university or literary college connection or affiliation. Only two colleges (located in Chicago) impart instruction exclusively in the evening, and three colleges have both day and evening classes.

Comparative Table of Medical Colleges.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880......	72	12	6	..	90
1890......	93	14	9	..	116
1900......	121	22	8	..	151
1901......	124	21	10	4	159
1902......	121	20	10	4	155
1903......	121	19	10	4	154
1904......	133	19	10	4	166
1905......	126	18	7	4	157

Seventy regular colleges are members of the Association of American Medical Colleges; 14 belong to the Southern Medical College Association; all the homeopathic colleges are recognized as in good standing by the college committee of the American Institute of Homeopathy, and all the eclectic colleges are members of the National Confederation of Eclectic Medical Colleges.

The comparative table of medical colleges shows that the raising of entrance requirements has been effective, in a measure, in reducing the number of colleges. In many of the colleges the number of students in attendance was so small that the college authorities were confronted with the necessity of either effecting an amalgamation with some other college or of passing out of existence. The expense of conducting an up-to-date medical college is greater than the income from a small number of students; hence, stockholders are confronted by an assessment levy which they have no desire to meet. On the other hand, college authorities are recognizing more and more the desirability, for the sake of improving medical education, of having fewer and better medical colleges.

Length of Terms.—Here, too, the upward tendency of educational matters is noticeable. Last year 56.8 per cent. of the colleges had terms of less than eight months' duration, whereas this year only 39 per cent. were in this class. Last year the number of colleges having a six months' term was 27 (16.3 per cent.), whereas this year there were only 15 schools (9.4 per cent.) Last year only 19 colleges (11.6 per cent.) had a session of nine months' duration. This year there were 38 colleges (24 per cent.)

Table of College Terms.†

	Schools.		Per cent.	
6 months................	(27)	15	*(16.3)*	*9.4*
7 months................	(44)	35	(27.0)	22.0
7½ months................	(22)	12	(13.5)	7.6
8 months................	(34)	46	(20.8)	29.0
8½ months................	(13)	10	(7.9)	6.1
9 months................	(19)	38	(11.6)	24.0
*10 months................	(4)	3	(2.4)	1.9

†Figures in brackets are for year 1904.
*Night schools.

Most of the colleges having six months' sessions are located in sections of the country where educators claim the educational facilities are such as to prohibit terms of longer duration. Most of the homeopathic and eclectic colleges have seven months' sessions. As we have pointed out before, the term "months" is exceedingly elastic. It always includes vacation periods. It is to be hoped that ere long this term will be discarded for "weeks." The college and state examining boards associations have substituted a requirement of thirty weeks, exclusive of holidays, for that of seven months. It is the equivalent of the old requirement of eight months. We have had no reason to change our opinion expressed last year that the ideal way of specifying the length of a college term is by requiring attendance in college for a definite number of hours in each subject taught.

Of the total number of matriculants, about 1.8 per cent. attended the night schools. About 24 per cent. attended colleges having sessions of nine months each. About 37.8 per cent. attended colleges having eight to eight and one-half months' sessions; 27.5 per cent. attended colleges having seven and seven and one-half months' sessions, while only 8.9 per cent. attended six months' sessions. Thus it will be seen that over one-half (61.8 per cent.) of the total number of students registered attended colleges whose sessions average from eight to nine months, whereas only 36.4 per cent. attended the short-term colleges. It is evident, therefore, that the length of the term does not sway the student in his selection of a college, because the majority of students attended the long-term colleges. Students are more and more taking into consideration the standing of the college and what it has to offer. Fees, entrance requirements and length of term are secondary considerations with the better class of students.

THE INFLUENCE OF THE PRIVATE PHYSICIAN ON MEDICAL EDUCATION.

The private practitioner, wherever located, is often likely to feel merely a remote interest in the great subject of medical education. He finished his own undergraduate medical education perhaps years ago, secured

MEDICAL EDUCATION IN THE UNITED STATES.

The present issue of The Journal contains statistics regarding medical education in the United States for the year ending June 30, 1905. The data published herein were obtained directly from the college authorities, from the annual announcements, and from other sources, and especial care has been taken to insure correctness in every instance. We have had the co-operation of practically all the colleges in this work, and we take this opportunity of extending our thanks to those who assisted us in gathering the statistics.

A careful study of the tables will show that medical education has undergone many changes during the past year. The standards of preparation of study and of graduation have been raised considerably, showing that there is a disposition on the part of all concerned to elevate the standard of the profession by bringing into it men and women who are better prepared to practice medicine, and who will be a credit to the profession in every way. There has been a distinct gain in the entrance requirements during the past two or three years. This change for the better is due, in part, to a few individual colleges, but largely it is the result of concerted action on the part of several organizations which have it in their power to promulgate and enforce rules and regulations for the government of colleges. The state examining boards, in particular, have exercised a most wholesome influence by raising the requirements and by taking an active part in the regulation of preliminary or preparatory education.

Number of Medical Students.—The total number of medical students (matriculants) in the United States for the year ending June 30, 1905, was 26,147, a decrease of 1,995 below the year 1904. Of this number 24,119 were in attendance at the regular schools, 1,104 at the homeopathic, 578 at the eclectic, 114 at the physiomedical, and 232 at the nondescript (unclassifiable) school. The attendance at the regular schools shows a slight increase—457—over that of last year, and a decrease—801—below 1903, and also a decrease —759—below 1902. In the homeopathic schools, there was a decrease of 205 below the attendance of 1904, 394 below 1903. In fact, the attendance at the homeopathic schools has been diminishing steadily since 1900. It was less last year than it has ever been since 1880. Up to the present year, the eclectic schools showed an increase in attendance since 1900. This year, however, the attendance fell to 578, 436 less than for 1904, and the lowest attendance since 1880. The attendance at the physiomedical schools has also fallen off a trifle. In 1904 the attendance at these three schools was 129. In 1905 it was 114.

Table of Medical College Attendance.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med and Nondescript.	Total.
1880......	9,776	1,220	830	....	11,826
1890......	13,521	1,164	719	...	15,404
1900......	22,710	1,909	552	...	25,171
1901......	23,846	1,683	664	224	26,417
1902......	24,878	1,617	765	241	27,501
1903......	24,930	1,498	848	339	27,615
1904......	23,662	1,309	1,014	357	28,142
1905......	24,119	1,104	578	346	26,147

These figures tend to show that the attendance at the regular schools is increasing at the expense of that at the sectarian schools. It is evident that the raising of the entrance requirements has been a factor in the lessening of the number of matriculants.

Graduates.—The total number of graduates for the year ending June 30, 1905, was 5,606, a decrease of 141 below the preceding year and 92 below the year 1903. The lowest number of graduates since 1900 was 4,999, in 1902; the highest number was 5,747, in 1904. For the year just closed the percentage of graduates to matriculants was 21.4. For 1904 it was 30.3; for 1903 it was 22.8. The decrease in the number of graduates from the regular colleges in 1905 was 64; from the homeopathic colleges, 95. The number of graduates from the eclectic colleges is 7 greater than it was last year, and 9 in the case of the unclassified college. The graduates of 1905 from the homeopathic colleges have been fewer in number than in any year since 1880. The electic schools, on the other hand, graduated more students in 1905 than in any year since 1890.

Table of Medical College Graduates.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880......	2,673	380	188	..	3,241
1890......	3,853	380	221	..	4,454
1900......	4,715	413	86	..	5,214
1901......	4,879	387	148	..	5,444
1902......	4,498	336	138	27	4,999
1903......	5,088	420	149	41	5,698
1904......	5,190	371	146	40	5,747
1905......	5,126	276	153	51	5,606

Women in Medicine.—During the past year 1,073 women were engaged in the study of medicine—4.1 per cent. of the total number of medical students, and 219 graduated—4 per cent. of the total number of graduates. In 1904 there were 1,129 women students, and 244 graduated. The proportion of female and male students was practically the same as last year. Of the total number of matriculants, only 221 (20.6 per cent.) were in attendance at the three colleges for women, and 54 (24.5 per cent.) graduated from them. The remaining number matriculated in and graduated from coeducational colleges.

Number of Colleges.—During the past year a number of colleges united, and several became extinct, so that at the present time there are 157 medical colleges in the United States (including the Philippine Islands). The medical department of the University of Porto Rico has not yet been organized and will not be for some time, but was included in our last year's statistics as an active college. Of the total number of colleges, 126 are regular, 18 homeopathic, 9 eclectic, 3 physiomedical, and 1 unclassified. During the year 2 homeopathic colleges united, and 1 eclectic college changed its faith and is now teaching regular medicine. Six of the regular colleges listed in our tables did not confer degrees, teaching only the first and second years of the medical course. Three colleges (two regular and one homeopathic) are exclusively for women; 63 for men; 91 are coeducational (66 regular, 13 homeopathic, 8 eclectic, 3 physiomedical, and 1 unclassified college). There are five schools to which only colored students are admitted, two less than last year, one having become extinct and the other now admitting both white and colored students. Three schools operate under the continuous course system, the year being divided into quarters, and the student being allowed to attend only a specified number of quarters or semesters in each calendar year. These three schools are located in Chicago. Sixty-eight regular colleges, 4 homeopathic and 1 eclectic college has a university or literary college connection or affiliation. Only two colleges (located in Chicago) impart instruction exclusively in the evening, and three colleges have both day and evening classes.

Comparative Table of Medical Colleges.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880......	72	12	6	..	90
1890......	93	14	9	..	116
1900......	121	22	8	..	151
1901......	124	21	10	4	159
1902......	121	20	10	4	155
1903......	121	19	10	4	154
1904......	133	19	10	4	166
1905......	126	18	7	4	157

Seventy regular colleges are members of the Association of American Medical Colleges; 14 belong to the Southern Medical College Association; all the homeopathic colleges are recognized as in good standing by the college committee of the American Institute of Homeopathy, and all the eclectic colleges are members of the National Confederation of Eclectic Medical Colleges.

The comparative table of medical colleges shows that the raising of entrance requirements has been effective, in a measure, in reducing the number of colleges. In many of the colleges the number of students in attendance was so small that the college authorities were confronted with the necessity of either effecting an amalgamation with some other college or of passing out of existence. The expense of conducting an up-to-date medical college is greater than the income from a small number of students; hence, stockholders are confronted by an assessment levy which they have no desire to meet. On the other hand, college authorities are recognizing more and more the desirability, for the sake of improving medical education, of having fewer and better medical colleges.

Length of Terms.—Here, too, the upward tendency of educational matters is noticeable. Last year 56.8 per cent. of the colleges had terms of less than eight months' duration, whereas this year only 39 per cent. were in this class. Last year the number of colleges having a six months' term was 27 (16.3 per cent.), whereas this year there were only 15 schools (9.4 per cent.) Last year only 19 colleges (11.6 per cent.) had a session of nine months' duration. This year there were 38 colleges (24 per cent.)

Table of College Terms.†

	Schools.		Per cent.	
6 months..................	(27)	15	(16.3)	9.4
7 months..................	(44)	35	(27.0)	22.0
7½ months..................	(22)	12	(13.5)	7.6
8 months..................	(34)	46	(20.8)	29.0
8½ months..................	(13)	10	(7.9)	6.1
9 months..................	(19)	38	(11.6)	24.0
*10 months..................	(4)	3	(2.4)	1.9

†Figures in brackets are for year 1904.
*Night schools.

Most of the colleges having six months' sessions are located in sections of the country where educators claim the educational facilities are such as to prohibit terms of longer duration. Most of the homeopathic and eclectic colleges have seven months' sessions. As we have pointed out before, the term "months" is exceedingly elastic. It always includes vacation periods. It is to be hoped that ere long this term will be discarded for "weeks." The college and state examining boards associations have substituted a requirement of thirty weeks, exclusive of holidays, for that of seven months. It is the equivalent of the old requirement of eight months. We have had no reason to change our opinion expressed last year that the ideal way of specifying the length of a college term is by requiring attendance in college for a definite number of hours in each subject taught.

Of the total number of matriculants, about 1.8 per cent. attended the night schools. About 24 per cent. attended colleges having sessions of nine months each. About 37.8 per cent. attended colleges having eight to eight and one-half months' sessions; 27.5 per cent. attended colleges having seven and seven and one-half months' sessions, while only 8.9 per cent. attended six months' sessions. Thus it will be seen that over one-half (61.8 per cent.) of the total number of students registered attended colleges whose sessions average from eight to nine months, whereas only 36.4 per cent. attended the short-term colleges. It is evident, therefore, that the length of the term does not sway the student in his selection of a college, because the majority of students attended the long-term colleges. Students are more and more taking into consideration the standing of the college and what it has to offer. Fees, entrance requirements and length of term are secondary considerations with the better class of students.

THE INFLUENCE OF THE PRIVATE PHYSICIAN ON MEDICAL EDUCATION.

The private practitioner, wherever located, is often likely to feel merely a remote interest in the great subject of medical education. He finished his own undergraduate medical education perhaps years ago, secured his license to practice, and, occupied each day with his own work, he begins to feel more or less instinctively *that the circle of his immediate influence is getting to* be well defined. More or less remote from the medical centers, he finds that there is little occasion for him to take any concern in the welfare and progress of the numerous institutions that are carrying on the actual work of training the coming generations of medical men. The methods and machinery of medical study even in his own college are now widely different from these in vogue when he "sat on the benches"; the requirements are different, the annual announcements, of which a number reach him each year, are couched in phrases that convey no definite meaning on cursory glance. Nevertheless, the physicians of the country can and do exercise a powerful influence on medical education, particularly in their close and often confidential relations to the young men in the community who want to study medicine. It is true that in these days of advancing entrance requirements when many students pass directly from the college to the medical school, the old time preceptor has lost prestige, but in spite of that physicians of standing everywhere frequently are called on to counsel young men in regard to the study of medicine; and there is much responsibility in the advisory capacity that physicians assume toward prospective medical students. In the first place, the physician must determine in his own mind whether the applicant for advice is by nature and training properly qualified in mind and morals to be encouraged in his often hastily conceived aspirations. Unquestionably, much disappointment and many disgraceful failures, early as well as late, may be avoided by firmly urging on the manifestly unfit the folly of an effort he can not sustain. Assuming, on the other hand, that there is no evident lack of fundamental qualifications, what are some of the general considerations that should guide the physician in his advice to a young man about to study medicine?

Preliminary Educational Requirements.—As yet there is great latitude on this point on the part of our medical colleges and of our state boards of health in the matter of preliminary educational requirements, but there is a general consensus of opinion that the minimum is a first class high school education; and it must be remembered that this does not suffice for admission to our best equipped schools, which require either part or all of the usual college course, with special attention to physics, biology and chemistry and to French and German. Hence, at the very outset, a serious problem must be settled without prejudice, if possible, to the fullest achievable success in medicine. The question the physician must determine in his own mind, after giving due regard to the individual peculiarities of each case, is which course is more likely to give the greater power, the higher ideals, the better service. We believe that if physicians will consider carefully this question the result will be to the advantage of the standing and efficiency of the profession in this country.

The Medical School.—What are the essential qualifications that a medical school must possess in order to merit the recommendation of the conscientious physician in his advice to the prospective medical student? In the first place, it is evident that it must fulfill the essential requirements of the various boards of state examiners, because it would be unjust to send a student to a school the graduates of which are not generally recognized by state boards. Such schools exist and their graduates consequently carry a most serious handicap when it comes to the selection of the scene of their life work. The following are some of the points that should be considered in the selection of the school:

1. *Equipment and Resources for Teaching the So-called Fundamental Branches, Anatomy, Physiology, and Physiologic Chemistry, Bacteriology, Pathology, Pharmacology.*—It is a recognized fact that a thorough grounding in the fundamental elements of these sciences is necessary in order that the medical student to-day may be properly prepared for the study of the practical or clinical branches. In order to teach properly to medical students the fundamental branches suitable, well-equipped, but not necessarily elaborate or ornate laboratories are essential. Each laboratory or department must be under the charge of a specially qualified man, who, as a rule, should give his whole time to teaching and investigation in his branches. Depending on the number of students and special circumstances there must be in each department a variable number of assistants. It is a recognized pedagogical principle that in elementary laboratory courses there should be at least one instructor for every 10 or 15 students. Anatomy and pathology require human material in order to give adequate instruction and in many of our schools there certainly is a lamentable lack of fresh pathologic material for the study of the gross changes of disease. Manifestly, large sums of money are necessary in order to do this work satisfactorily, money for permanent buildings and equipment, and for annual appropriations for salaries and current expenses. It should be realized that on account of the changes in the past fifteen years or so in the teaching of the fundamental branches, the income from the fees of students no longer suffices to pay for the running of a medical school on a satisfactory basis. Endowments and university connections are necessary.

2. *Equipment and Resources for Teaching the Clinical Branches.*—We are agreed that the day of slovenly dispensary teaching, of the routine clinical lecture, of the crowded amphitheatrical surgical and medical clinic is past. Small classes, individual instruction, bedside work, practical obstetric work, and work in the clinical laboratories are now considered essential in order that the student may become directly and personally familiar with the actual manifestations and methods of treatment of disease. In order to do this, the school must have undivided control of adequate dispensary and hos-

pital facilities and the various clinical departments must be thoroughly organized, so that proper co-ordination is attained. This is the largest weak spot in our medical schools, taken as a whole, and fortunate is the student who is wisely guided in this respect. Attention also may be called to the fact that progressive clinicians, for evident reasons, no longer are satisfied with having their laboratory work "farmed out," and as a consequence the well-equipped medical, surgical and gynecologic clinic each has its own laboratory.

3. *Library.*—In order that the student may secure some idea of the character of the literature of medicine in a broad sense, in order that he may be trained in the use of medical literature, in order that he may learn the necessity of following the main lines of development of medicine, if he wishes to grow and not to fossilize as soon as he leaves the medical school, and for other reasons, not the least of which are the needs of the faculties themselves, libraries are now an essential part of the equipment of the modern medical school. There has been a gratifying growth of interest in medical libraries in the United States during the last few years and several medical schools are now in possession of good libraries, from which students derive great inspiration and benefit. Unfortunately, however, the majority of our schools are not so favored and in numerous instances access can not be had to any medical library because there are large sections of the country that as yet are barren of library facilities. Here is a golden opportunity for physicians to influence medical education directly as well as indirectly, by joining hands in efforts to remedy this great need.

4. *Location.*—Other things being equal the location of a medical school is well worth consideration in the interest of the student. The majority of our schools are located in the larger cities, many of them in undesirable districts, in which vice in various forms flourishes rankly. The kind physician will hesitate in sending young men into the midst of such surroundings in preference to other places with a clearer, purer atmosphere. In this connection, it may not be out of order to ask what are the schools doing for the moral and physical welfare of the student? What about club rooms, gymnasiums, athletic fields, libraries and other influences for a healthy life?

Many other points must be omitted, such as the composition and the manner of appointment of the faculties, the arrangement of the curriculum, the records of the schools as to scientific investigation by the members of the faculties, the night school, etc.

The private physician has the power to influence medical education effectively by taking an interest in medical legislation in the various states. At every session of the state legislature questions of great moment to medical education and on which the members of the legislature need trusted and unselfish advice come up for discussion. Right here is an opportunity for effective influence that there is reason to fear physicians too often neglect. We see that both in his private as well as in his public relations the physician, wherever he may be, has placed on him certain responsibilities with reference to medical education which, if discharged conscientiously and high-mindedly, can not but have a far-reaching influence.

NATURAL RACE IMMUNITY.

Formerly it was believed that some human races possessed an absolute immunity to certain specific infectious diseases. Yellow fever, for instance, was supposed and is regarded even now as of little or no danger to negroes. The natives in yellow fever districts were said to escape the disease because they were "acclimatized." Livingstone declared that the native African was immune to syphilis, but unfortunately it has turned out that in this case the supposed immunity meant only this, that up to that time and for some time afterward syphilis had not been introduced into those parts of Africa traversed by the great explorer. So also has it been claimed that negroes are immune or but little susceptible to the malarial diseases. On the other hand, the colored race has been regarded as peculiarly susceptible to smallpox.

With the gradual growth of exact knowledge in regard to the spread of infectious diseases in all parts of the world, the belief that any human race possesses any absolute insusceptibility to the diseases just mentioned and to others of a similar character is gradually changing. What at first has seemed to be a natural, inborn immunity is, little by little, found to be in reality either a relatively high resistance, the consequence of acquired immunity, or the mistaken result of a prolonged absence of the opportunity for infection to develop.

The different behavior of the same infectious diseases among different races in the same country, as shown, for instance, by the relative infrequency of bubonic pest in Europeans in India and elsewhere as compared with its great frequency among the poorer classes of the natives, finds its true explanation not in any real insusceptibility on the part of the Europeans but in the different conditions that obtain as to cleanliness and general hygiene. The Europeans, in consequence of better hygiene, are not so exposed to infection, and, if exposed, perhaps better able to withstand it because of a greater general but non-specific resistance by virtue of better food and better care of the body in general. The same general observations may be made with reference to cholera. Knowing the sources of the disease, the intelligent civilized man is able to avoid it, while the poor native freely exposes himself to infection.

The Jews of western Europe have, relatively, little tuberculosis. This is not due to any true race immunity, as shown by the prevalence of the disease among the less favored members of this race in Poland, Russia, and in the ghettos of our own large cities.

The idea that the natives of South Africa were im-his license to practice, and, occupied each day with his own work, he begins to feel more or less instinctively that the circle of his immediate influence is getting to be well defined. More or less remote from the medical centers, he finds that there is little occasion for him to take any concern in the welfare and progress of the numerous institutions that are carrying on the actual work of training the coming generations of medical men. The methods and machinery of medical study even in his own college are now widely different from these in vogue when he "sat on the benches"; the requirements are different, the annual announcements, of which a number reach him each year, are couched in phrases that convey no definite meaning on cursory glance. Nevertheless, the physicians of the country can and do exercise a powerful influence on medical education, particularly in their close and often confidential relations to the young men in the community who want to study medicine. It is true that in these days of advancing entrance requirements when many students pass directly from the college to the medical school, the old time preceptor has lost prestige, but in spite of that physicians of standing everywhere frequently are called on to counsel young men in regard to the study of medicine; and there is much responsibility in the advisory capacity that physicians assume toward prospective medical students. In the first place, the physician must determine in his own mind whether the applicant for advice is by nature and training properly qualified in mind and morals to be encouraged in his often hastily conceived aspirations. Unquestionably, much disappointment and many disgraceful failures, early as well as late, may be avoided by firmly urging on the manifestly unfit the folly of an effort he can not sustain. Assuming, on the other hand, that there is no evident lack of fundamental qualifications, what are some of the general considerations that should guide the physician in his advice to a young man about to study medicine?

Preliminary Educational Requirements.—As yet there is great latitude on this point on the part of our medical colleges and of our state boards of health in the matter of preliminary educational requirements, but there is a general consensus of opinion that the minimum is a first class high school education; and it must be remembered that this does not suffice for admission to our best equipped schools, which require either part or all of the usual college course, with special attention to physics, biology and chemistry and to French and German. Hence, at the very outset, a serious problem must be settled without prejudice, if possible, to the fullest achievable success in medicine. The question the physician must determine in his own mind, after giving due regard to the individual peculiarities of each case, is which course is more likely to give the greater power, the higher ideals, the better service. We believe that if physicians will consider carefully this question the result will be to the advantage of the standing and efficiency of the profession in this country.

The Medical School.—What are the essential qualifications that a medical school must possess in order to merit the recommendation of the conscientious physician in his advice to the prospective medical student? In the first place, it is evident that it must fulfill the essential requirements of the various boards of state examiners, because it would be unjust to send a student to a school the graduates of which are not generally recognized by state boards. Such schools exist and their graduates consequently carry a most serious handicap when it comes to the selection of the scene of their life work. The following are some of the points that should be considered in the selection of the school:

1. *Equipment and Resources for Teaching the So-called Fundamental Branches, Anatomy, Physiology, and Physiologic Chemistry, Bacteriology, Pathology, Pharmacology.*—It is a recognized fact that a thorough grounding in the fundamental elements of these sciences is necessary in order that the medical student to-day may be properly prepared for the study of the practical or clinical branches. In order to teach properly to medical students the fundamental branches suitable, well-equipped, but not necessarily elaborate or ornate laboratories are essential. Each laboratory or department must be under the charge of a specially qualified man, who, as a rule, should give his whole time to teaching and investigation in his branches. Depending on the number of students and special circumstances there must be in each department a variable number of assistants. It is a recognized pedagogical principle that in elementary laboratory courses there should be at least one instructor for every 10 or 15 students. Anatomy and pathology require human material in order to give adequate instruction and in many of our schools there certainly is a lamentable lack of fresh pathologic material for the study of the gross changes of disease. Manifestly, large sums of money are necessary in order to do this work satisfactorily, money for permanent buildings and equipment, and for annual appropriations for salaries and current expenses. It should be realized that on account of the changes in the past fifteen years or so in the teaching of the fundamental branches, the income from the fees of students no longer suffices to pay for the running of a medical school on a satisfactory basis. Endowments and university connections are necessary.

2. *Equipment and Resources for Teaching the Clinical Branches.*—We are agreed that the day of slovenly dispensary teaching, of the routine clinical lecture, of the crowded amphitheatrical surgical and medical clinic is past. Small classes, individual instruction, bedside work, practical obstetric work, and work in the clinical laboratories are now considered essential in order that the student may become directly and personally familiar with the actual manifestations and methods of treatment of disease. In order to do this, the school must have undivided control of adequate dispensary and hos-

pital facilities and the various clinical departments must be thoroughly organized, so that proper co-ordination is attained. This is the largest weak spot in our medical schools, taken as a whole, and fortunate is the student who is wisely guided in this respect. Attention also may be called to the fact that progressive clinicians, for evident reasons, no longer are satisfied with having their laboratory work "farmed out," and as a consequence the well-equipped medical, surgical and gynecologic clinic each has its own laboratory.

3. *Library.*—In order that the student may secure some idea of the character of the literature of medicine in a broad sense, in order that he may be trained in the use of medical literature, in order that he may learn the necessity of following the main lines of development of medicine, if he wishes to grow and not to fossilize as soon as he leaves the medical school, and for other reasons, not the least of which are the needs of the faculties themselves, libraries are now an essential part of the equipment of the modern medical school. There has been a gratifying growth of interest in medical libraries in the United States during the last few years and several medical schools are now in possession of good libraries, from which students derive great inspiration and benefit. Unfortunately, however, the majority of our schools are not so favored and in numerous instances access can not be had to any medical library because there are large sections of the country that as yet are barren of library facilities. Here is a golden opportunity for physicians to influence medical education directly as well as indirectly, by joining hands in efforts to remedy this great need.

4. *Location.*—Other things being equal the location of a medical school is well worth consideration in the interest of the student. The majority of our schools are located in the larger cities, many of them in undesirable districts, in which vice in various forms flourishes rankly. The kind physician will hesitate in sending young men into the midst of such surroundings in preference to other places with a clearer, purer atmosphere. In this connection, it may not be out of order to ask what are the schools doing for the moral and physical welfare of the student? What about club rooms, gymnasiums, athletic fields, libraries and other influences for a healthy life?

Many other points must be omitted, such as the composition and the manner of appointment of the faculties, the arrangement of the curriculum, the records of the schools as to scientific investigation by the members of the faculties, the night school, etc.

The private physician has the power to influence medical education effectively by taking an interest in medical legislation in the various states. At every session of the state legislature questions of great moment to medical education and on which the members of the legislature need trusted and unselfish advice come up for discussion. Right here is an opportunity for effective influence that there is reason to fear physicians too often neglect. We see that both in his private as well as in his public relations the physician, wherever he may be, has placed on him certain responsibilities with reference to medical education which, if discharged conscientiously and high-mindedly, can not but have a far-reaching influence.

NATURAL RACE IMMUNITY..

Formerly it was believed that some human races possessed an absolute immunity to certain specific infectious diseases. Yellow fever, for instance, was supposed and is regarded even now as of little or no danger to negroes. The natives in yellow fever districts were said to escape the disease because they were "acclimatized." Livingstone declared that the native African was immune to syphilis, but unfortunately it has turned out that in this case the supposed immunity meant only this, that up to that time and for some time afterward syphilis had not been introduced into those parts of Africa traversed by the great explorer. So also has it been claimed that negroes are immune or but little susceptible to the malarial diseases. On the other hand, the colored race has been regarded as peculiarly susceptible to smallpox.

With the gradual growth of exact knowledge in regard to the spread of infectious diseases in all parts of the world, the belief that any human race possesses any absolute insusceptibility to the diseases just mentioned and to others of a similar character is gradually changing. What at first has seemed to be a natural, inborn immunity is, little by little, found to be in reality either a relatively high resistance, the consequence of acquired immunity, or the mistaken result of a prolonged absence of the opportunity for infection to develop.

The different behavior of the same infectious diseases among different races in the same country, as shown, for instance, by the relative infrequency of bubonic pest in Europeans in India and elsewhere as compared with its great frequency among the poorer classes of the natives, finds its true explanation not in any real insusceptibility on the part of the Europeans but in the different conditions that obtain as to cleanliness and general hygiene. The Europeans, in consequence of better hygiene, are not so exposed to infection, and, if exposed, perhaps better able to withstand it because of a greater general but non-specific resistance by virtue of better food and better care of the body in general. The same general observations may be made with reference to cholera. Knowing the sources of the disease, the intelligent civilized man is able to avoid it, while the poor native freely exposes himself to infection.

The Jews of western Europe have, relatively, little tuberculosis. This is not due to any true race immunity, as shown by the prevalence of the disease among the less favored members of this race in Poland, Russia, and in the ghettos of our own large cities.

The idea that the natives of South Africa were immune to malaria was shown to be without any basis in fact by R. Koch, who found that the disease is prevalent among the African children and that the small degree of susceptibility of the adults is due to a true acquired immunity. There is abundant reason to believe that an acquired immunity also explains the alleged natural insusceptibility to yellow fever on the part of the natives in districts in which this disease is endemic. It is to be borne in mind that a severe attack is not necessary for the establishment of an acquired immunity. It is quite probable that children, possibly to some degree protected by an intrauterine transfer of antibodies, may pass through comparatively mild attacks that are hardly noticed.

We know, too, that infectious diseases that have existed for a long time in a given country gradually appear in less and less virulent form among the people. This is certainly true as regards measles and possibly also scarlet fever, which, when introduced on virgin soil, e. g., the Faro or Sandwich Islands, assume a virulent type.

The increased attention given to tropical diseases, the continued and augmented necessity to guard against the introduction of infectious diseases prevalent among the civilized races into countries occupied by races as yet but little advanced on the road to civilization, and *vice versa,* are going to give us more definite information in regard to this question of true race immunity, the existence of which at the present time appears to be exceedingly doubtful.

THE EPIDEMIC CONTINUES.

The number of cases of yellow fever in New Orleans has steadily increased. On August 15, the total of cases reported to that date was 1,122 and total deaths 184, a mortality of 16.4 per cent., showing decreasing death rate. Scientific medicine can not accomplish the impossible, and the conditions in New Orleans have made inevitable some extension of the epidemic. It is greatly to be regretted that some few physicians undoubtedly have shared in the concealment of patients at points which have thereby become new foci of infection before they were discovered. Other patients have gone without medical care rather than submit to preventive measures. From such patients a large number of mosquitoes have become infected and, of course, are spreading the disease. It must not be overlooked that New Orleans is not under military government, with a physician at the head of affairs, as was Havana when yellow fever was exterminated there. This difference in conditions is all-important. Many landlords and tenants have not complied with the new ordinance to screen cisterns and houses, and they are to be arrested and prosecuted. Even rich men in the best part of New Orleans have been offenders. Up to this time the cases in the American quarter of the city are few and scattered, while in the old quarter the infection has become pretty general. Dr. Berry, of the United States Public Health and Marine-Hospital Service, thought to be immune by reason of a former attack, has unfortunately suffered a severe infection of the fever, and scoffers at the mosquito etiology have made what they could of the alleged fact that he had been sleeping under a screen. Later and more accurate reports will, without doubt, clear up these features of the case. In view of the fact that the health authorities are not receiving quite unanimous public support, it is hopeless to expect an early cessation of the epidemic. The best that can come under such conditions is a reduction in the number of cases and restriction of the spread, though Louisiana, outside New Orleans, now reports many foci. The freedom of a republic is unfavorable to the extermination of an epidemic. By the time the people can express themselves and obtain the necessary laws the necessity for such has passed. Legal processes are too slow to effect prevention. The time may yet come when we shall find it advisable to give full and real military power to our health authorities during epidemics. Communities are now quite willing that boards of health shall have military power as against other communities, but domiciliary inspection and its accompanying restrictions and requirements is not received with general favor. Military enforcement of orders to screen, to clean up, to report suspicious illness, etc., is not desired, but we shall, perhaps, have to come to it if ordinary measures are not responded to more heartily. When this epidemic is over we shall have accumulated a fund of new and useful information obtained in the school of practical experience.

THE TABLE OF STATISTICS OF COLLEGES.

On pages 566 and 567 will be found a table, giving the states containing medical colleges, the name of each college, the population of the city in which the college is located, the number of men and women registered as students during the session of 1904-05, and also the graduates (men and women) of 1905, the total number of teachers in each college, and the number of weeks in the college year. The suffixes, R., H., E., Ph.M., stand for regular, homeopathic, eclectic and physiomedical. Much of the information to be derived from this table has been set forth in the editorial on Medical Education in the United States, page 536. On page 552 we present, in abstract form, essential facts of all medical colleges arranged by states, and on pages 565 and 566 will be found the requirements of the regular, homeopathic, and eclectic medical college associations, also a list of colleges holding membership in these organizations.

EPIDEMIOPHOBIA.

Medical men long have wondered at the inconsistencies of the popular dread of epidemics. People and newspapers became hysterical a few years ago over a score or two cases of Asiatic cholera on the seaboard, while around their offices and homes thousands suffered and died from tuberculosis, syphilis, gonorrhea and typhoid. The small but new enemy seemed infinitely more terrible than the great but familiar ones. The newspapers of August 11 presented a dramatic example of the same peculiar mode of thought. New Orleans reported a total to that date of 756 cases of yellow fever, with a total of 129 deaths, nearly all the mortality being among the Italians. New York reported up to August 5, 1,496 cases of typhoid, with 395 deaths, many of them among Americans of the better class. Think of the fright, brutality and migration inspired by the smaller figures as compared with the virtual indifference that meets the greater ones! Yet we know that, apart from popular apathy, it is easier wholly to prevent typhoid in the North than yellow fever in the South. Uncontaminated water and food insure freedom from epidemic typhoid, while the prevention of yellow fever necessitates the destruction of myriads of insects as well as the absolute isolation from the mosquitoes of every case of the disease during the first three days of fever. Verily man is yet an illogical animal.

DISTRIBUTION OF MEDICAL STUDENTS.

On pages 568 to 571 will be found a table showing the distribution of students of each college by states. The influence of the proximity of the medical school is seen in the fact that states which have medical colleges have more students in proportion to the population than those which have none. Only three states contributed over two thousand students: New York, 2,423; Illinois, 2,084; Pennsylvania, 2.022. Four states contributed over one thousand students, but less than two thousand: Missouri, 1,138; Ohio, 1,065; Massachusetts, 1,019; Texas, 1,012. Iowa contributed 916 students, and Indiana, 881. The fewest students (9) came from Arizona. Wyoming and Nevada each contributed 13 students; New Mexico, 19; Montana, 30; Idaho, 37; Delaware, 48; Utah, 68; North Dakota, 70, and South Dakota, 93. The states not mentioned contributed between 100 and 700 each. Several of the colleges failed to furnish the information necessary for this table, but, as most of them are small schools, the figures can be disregarded in summing up. Two of these schools are of some size, and, as the majority of their students come from Kentucky and Indiana, the totals of these two states would be increased considerably.

THE EVOLUTION OF INFECTION.

The editorial in The Journal, August 5, entitled "Declining Virulence and Advancing Parasitism" has caused a correspondent to call our attention to an article that appeared in The Journal, May 3, 1890, written by Bayard Holmes of Chicago, in which infectious parasitism is discussed from the same general point of view, i. e., the evolutionary, as in Theobald Smith's address. When Holmes wrote his article our knowledge of the finer mechanisms of the establishment and healing of bacterial infections was in its very beginning; the life history, the mechanisms of ingress and egress, the distribution of most of the pathogenic microbes were as yet largely unknown. Consequently it was only the grosser facts of parasitism and of infection that could be used to construct any theories as to the evolution of infection, and this it must be said that Holmes did with great skill and farsightedness. After reviewing certain of the general facts of parasitism and especially those that indicate that the obligate parasites of tuberculosis, syphilis, measles, scarlet fever, etc., must have occupied long periods of time to become adapted to their present very restricted modes of existence, Holmes asks how has it been possible for man to withstand the attacks of so many enemies for so long a time? He answers that the reason is that the parasites were not essentially destructive; had they been so, neither host nor parasite would have survived; for with the destruction of the host species occurs the destruction of the parasite. The diseases mentioned may become more or less destructive, however, by virtue of secondary mixed infections and other accessory factors, such as all that tend to weaken the body. In the case of facultative parasites, on the other hand, the chances, so Holmes argued, are more against the host in the conflict that ensues, because natural selection has not rendered us indurate to them. It will be seen that Smith's theory goes much farther than Holmes' in that the former includes under his law of declining virulence and advancing parasitism, not only obligate parasites, but also the facultative invasive microbes, i. e., those that appear to be slowly moving, through long periods of time, toward higher degrees of parasitism.

THE EDUCATION OF THE PUBLIC.

The opportunity for public lectures on the subject of hygiene and prevention of disease in connection with the summer assemblies held at various points throughout the country is worthy of cultivation. An example lies before us in the illustrated announcement of the Rockford (Ill.) Chautauqua Assembly. Included in the program, which touches on every subject that might interest the popular audience, are several lectures on the tuberculosis problem by two physicians who are fully competent to speak thereon. Other assemblies have similar lectures, and we believe that if the authorities knew whom they could secure to give lectures of this kind there would be a much greater demand. Any county medical society, we think, will be able to recommend such speakers. In view of the public interest in medical matters, it is the duty of physicians to enlighten the public so that persons of immature or erratic ideas will not need to pose as exponents of the medical profession, as sometimes occurs. But—and this is important if criticism is to be avoided—great care must be taken by those who do this work that the methods adopted are strictly ethical.

Medical News

ILLINOIS.

Hospital Site Selected.—It has been decided that the new Warner Hospital, Clinton, is to be erected on West White Street. The ground is already being cleared.

Personal.—Dr. Buxbaum, Chicago, has succeeded Dr. Edward Banker as home physician of the St. Charles Hospital.——Dr. Louise L. Culver, Sandwich, sailed for Europe last week.——Dr. Charles E. Crawford, Rockford, has been elected grand medical examiner of the Sons of St. George.——Dr. Robert W. McInnes, Belvidere, has been appointed a member of the Jamestown centennial exposition commission.——Dr. Byron C. Stolp, has returned from Europe.——Dr. and Mrs. James C. Gill, Chicago, returned from Europe last week.

Chicago.

Ground Lease Recorded.—Rosa A. Henderson has recorded a ground lease of the Lakeside Hospital site to A. Ralph mune to malaria was shown to be without any basis in fact by R. Koch, who found that the disease is prevalent among the African children and that the small degree of susceptibility of the adults is due to a true acquired immunity. There is abundant reason to believe that an acquired immunity also explains the alleged natural insusceptibility to yellow fever on the part of the natives in districts in which this disease is endemic. It is to be borne in mind that a severe atttack is not necessary for the establishment of an acquired immunity. It is quite probable that children, possibly to some degree protected by an intrauterine transfer of antibodies, may pass through comparatively mild attacks that are hardly noticed.

We know, too, that infectious diseases that have existed for a long time in a given country gradually appear in less and less virulent form among the people. Medical News

ILLINOIS.

Hospital Site Selected.—It has been decided that the new Warner Hospital, Clinton, is to be erected on West White Street. The ground is already being cleared.

Personal.—Dr. Buxbaum, Chicago, has succeeded Dr. Edward Banker as home physician of the St. Charles Hospital.——Dr. Louise L. Culver, Sandwich, sailed for Europe last week.——Dr. Charles E. Crawford, Rockford, has been elected grand medical examiner of the Sons of St. George.——Dr. Robert W. McInnes, Belvidere, has been appointed a member of the Jamestown centennial exposition commission.——Dr. Byron C. Stolp, has returned from Europe.——Dr. and Mrs. James C. Gill, Chicago, returned from Europe last week.

Chicago.

Ground Lease Recorded.—Rosa A. Henderson has recorded a ground lease of the Lakeside Hospital site to A. Ralph

Johnstone for a term of ten years from Aug. 31, 1903, at an annual rental of $4,500, with privilege of purchase at any time for $60,000.

Physicians Play Golf.—The Physicians'.Golf Association, of which Dr. Franklin H. Martin is president and Dr. Thomas J. Watkins, secretary and treasurer, held its annual tournament at the Midlothian links August 10 and 11. Dr. Allan T. Haight won in the first flight; Dr. Franklin H. Martin the second; Drs. William H. Wilder and Thomas J. Watkins divided the third; Dr. Charles F. Swan won the fourth, and Dr. C. S. Stevenson the fifth.

Deaths of the Week.—For the week ended August 12, 539 deaths were recorded, equivalent to an annual death rate of 14.11 per 1,000. This is a decrease from 14.85, the rate for the previous week, but an increase over 13.41, the rate for the corresponding week of last year. Acute intestinal diseases caused 200 deaths; 222 deaths were of children under 5; heart disease killed 37; consumption, 36; violence, 35; nephritis and pneumonia, each 30. and cancer, 21.

IOWA.

Physician's House Burned.—The residence of Dr. John F. McKittrick, Des Moines, was burned to the ground July 27. The loss is estimated at $8,000.

European Tourists.—Dr. John N. Warren, Sioux City, has gone to Germany.——Dr. and Mrs. James J. Ransom, Burlington, have returned after a year abroad.

Demands Sanitary Cars.—Iowa has started a crusade against insanitary passenger cars and the disease-breeding conditions that characterize many of the coaches on western railroads. This step has been taken by the state medical board and boards in other states will be asked to co-operate in carrying the crusade to a successful issue. It is proposed to secure the thorough cleansing of the passenger coaches at the terminus of every trip, as well as to secure the co-operation of the railroads in preventing the spread of disease through the medium of unsanitary coaches and sleeping cars.

Personal.—Dr. Robert E. Conniff, Sioux City, has been elected president of the State Board of Health, and first vice-president of the Iowa Anti-Tuberculosis Association.——Dr. and Mrs. Jacob W. Wells, Ossian, have been committed to the Iowa Hospital for the Insane, Mount Pleasant, on account of drug addiction.——Dr. Reginald H. Payne, Van Horner, has taken a trip to the West Indies.——Dr. Clarence Hetzel, Davenport, has been appointed assistant physician at the Orphans' Home in that city.——Dr. George P. Neal, Fort Madison, has been appointed a state delegate to the Trans-Mississippi Commercial Congress, which meets in Portland, Ore., August 16-19.——Dr. Paul H. Schaefer, Burlington, has been elected physician of Des Moines County.

KENTUCKY.

Acquitted.—Dr. Edward C. Courtney, Neave, who shot and killed his partner, Dr. W. M. Carney during a "misunderstanding," in December last, was acquitted July 14 on the ground of self-defense.

Personal.—Dr. William M. Hanna, Henderson, has had a cerebral hemorrhage.——Dr. Edward Alcorn, Hustonville, is ill and under treatment in St. Joseph's Hospital, Lexington.——Dr. G. Z. Horine, Graefenburg, fell over a chair, breaking five ribs.——Dr. Irvin Abell, Louisville, who was operated on for appendicitis last month, is making a satisfactory recovery.——Dr. Robert C. H. Rademaker, Louisville, was found unconscious and suffering from a wound in the head July 26.——Dr. Alfred G. Farmer, Louisville, sailed August 14 for Panama.——Dr. Oscar E. Bloch has been appointed lecturer on surgery in the University of Louisville Medical Department.——Dr. J. Mason Morris, Louisville, is seriously ill at Battle Creek, Mich.

MARYLAND.

Bequest.—The Hebrew Hospital, Baltimore, has received a bequest of $1,000.

Insane Asylum Journal.—The *Maryland Hospital News* is a monthly four-page paper which emanates from Spring Grove Asylum for the Insane. It is edited by a patient and is believed to be the only paper of the kind in existence. It was first issued in 1899.

Personal.—Dr. H. Burton Stevenson, Sherwood, Baltimore County, had his left ankle broken while out driving.——Dr. Hugh Warren Brent, Baltimore, is in Berlin and will later go to Denmark.——Dr. William J. Watson, who was operated on for appendicitis, has recovered and has gone to West Virginia for the rest of August.

MASSACHUSETTS.

Donation to Lowell Hospital.—Frederick Fanning Ayer has given $50,000 to Lowell General Hospital, the income of which is to be used for such purposes as the trustees may decide.

Senior Student Drowned.—Walter L. Bradbury, Roxbury, a senior student at Tufts Medical College, who was employed as emergency physician at Nantasket Beach, was drowned at that place while swimming, July 30, aged 30.

Relief Hospital at East Boston.—The City Council of Boston has voted $30,000 for a relief hospital in East Boston, to be conducted like that at Haymarket Square, as a branch of the City Hospital. To this has been added the $11,000 available for the same purpose from the estate of Anne Taggart.

Automobilist Fined.—At the District Court in Dedham, Dr. Howard A. Lothrop, Boston, was fined $5 for speeding his automobile beyond the legal limit of 12 miles an hour. The explanation that he was going to a patient 83 years old in imminent danger of death did not avail in the eye of the law.

Personal.—Dr. Charles P. Thayer, Boston, secretary of Tufts Medical College, has resigned and has been succeeded by Dr. Frederic M. Briggs.——Dr. Hibbert W. Hill has resigned as director of the bacteriologic laboratory of the Boston Board of Health, to become assistant professor of bacteriology in the University of Minnesota and assistant director of the Minnesota State Board of Health laboratory.

MICHIGAN.

Abroad.—Dr. and Mrs. James Cleland, Jr., Detroit, sailed for Europe August 5.——Dr. and Mrs. Theophil Klingman, Ann Arbor, have gone to Europe.——Dr. Cressy L. Wilbur, Lansing, has sailed for Paris.

Hospital Notes.—Frank W. Hubbard, Bad Axe, has given $10,000 to build a hospital at that place, which it is said will be the only one in the Thumb of Michigan.——The Flint council has accepted the bequest of James J. Hurley of $25,000 and a site for a hospital to be known as the Hurley Hospital.——Mrs. Delia Alma Hanmer, Detroit, left by her will $10,000 to endow a room to be known as the Hanmer School of Music Room.

National Guard Changes.—On account of the resignation of Dr. John L. Burkart as major-surgeon of the Fourth Infantry, M. N. G., Captain William T. Dodge, Big Rapids, has been made major and surgeon; Lieutenant Ralph C. Apted, Grand Rapids, captain and assistant surgeon, and Dr. Howard A. Grube, Coldwater, lieutenant and assistant surgeon. Major Burkart is still in the United States service in the Philippine Islands.

Personal.—Dr. G. T. Richards of the medical staff of the Michigan Asylum for the Insane, Kalamazoo, has resigned, and Dr. Bert C. Stripp has been added to the staff.——Dr. James Cummings has been made director of the Pasteur Institute at the University of Michigan, vice Dr. Thomas B. Cooley, resigned.——Dr. Albert P. Ohlmacher, formerly of Gallipolis, Ohio, has been appointed director of the biologic laboratory of Frederick Stearns & Co., Detroit.——Dr. Oliver A. La Crone, Kalamazoo, is critically ill with rheumatic arthritis.

NEW YORK.

Diphtheria in Rochester.—During July 114 cases of diphtheria were reported in Rochester, with 9 deaths.

Fraud Order Issued.—The postmaster general has issued a fraud order against the New York Institute of Physicians and Surgeons and Prof. Thomas E. Adkins of Rochester, N. Y., its president. Newspaper advertisements in the shape of seeming news told of the wonderful "vitaopathic" treatment.

Memorial to Young Trudeau.—A memorial window has been placed in St. John's in the Wilderness, Paul Smith's, in the Adirondacks, in memory of the late Dr. Edward L. Trudeau, Jr. The window was unveiled last week, and shows a figure of a young man in the garb of a traveler with a caduceus in his right hand. Under the window is the inscription: "I will look unto the hills from which cometh my help. This window is placed here in loving memory of Dr. E. L. Trudeau, Jr., by his friends."

New York City.

Off for Europe.—Dr. Eugene Fuller sailed on the *New York*, August 11.——Dr. J. B. Zabriskie sailed on the *Minnehaha*, August 11.——Dr. Albert Leffingwell of Aurora sailed on the *Bremen*, August 10.

Smallpox in Harlem.—Two cases of this disease were discovered in Harlem on August 2. A daily inspection of the block in which they lived has been made since finding these cases, but no more cases as yet have occurred.

Destroying Bad Milk.—The summer corps of the Health Department has made several very thorough examinations of the milk supply of the city, with the result that thousands of gallons have been thrown away. Whenever the temperature of the milk is above 50 F. it is destroyed. The sanitary condition of the shops and utensils used in handling the milk has been improved.

Typhoid Fever at Bath Beach and Bay Ridge.—There are at present 173 cases of typhoid fever in three Brooklyn hospitals—the Norwegian, Seney and Long Island College. So many were leaving the vicinity that a meeting of citizens was held to consider what could be done to check the epidemic. They claimed that the situation was by no means as alarming as had been represented. The Board of Health has prepared a circular letter entitled "How to Avoid the Contraction and to Prevent the Spread of Typhoid Fever," which will be put into the hands of the people living in infected houses.

New Brooklyn Hospitals.—For years East New York and Canarsie have felt the need of an institution with an ambulance service, as the nearest hospitals are from two to five miles distant. The contemplated institution is to take the place of the Bradford Street Hospital, which is an old building entirely inadequate in every respect. A site has been purchased facing Linton Park at a cost of $36,000. The Department of Charities has $50,000 available for the erection of this structure. The building to be erected now will only be a small part of what is designed to build later.——The charities department also has plans drawn for another hospital in Brooklyn, to be built on the Ocean Parkway between Avenue Y and Canal Avenue. This institution will be devoted largely to convalescent patients, will have a capacity of 75 beds and will cost about $100,000.

OHIO.

Joint Meeting and Outing.—The first joint meeting of the Lake and Ashtabula County medical societies was held at the Shore Club, August 7. Dr. H. N. Amidon, Painesville, greeted the guests, and Dr. William H. Leet, Conneaut, responded. Dr. Harris G. Sherman, Cleveland, acted as toastmaster.

Receiver Appointed for Hospital.—On petition of Dr. Robert C. Tarbell, and by consent of the parties concerned, Judge Dillon of the Common Pleas Court, on July 29 appointed Dwight Harrison, an attorney of Columbus, receiver of the new Columbus General Hospital Company, under bond of $10,000.

Wagar Likes West.—Dr. Charles P. Wagar, Toledo, who went to Los Angeles several months ago, has returned to Toledo for the summer. He expects to remain on the Pacific Slope and has commenced the publication of the *California Medical and Surgical Reporter* in addition to the *Toledo Medical and Surgical Reporter*.

Ill and Injured.—Dr. Jared E. Cone, Youngstown, is reported critically ill with heart disease.——Dr. Charles C. Knapp, Zanesville, is reported to be seriously ill from rhus poisoning at a hospital in Portland, Ore.——Dr. Hugh A. Baldwin, Columbus, is able to be out on crutches after an illness of 18 months.——Dr. D. Van Buren Burkett, Columbus, who had both hips broken and sustained internal injuries, July 7, by being crushed between two street cars, is improving.——Dr. J. W. Haverfield, Uhrichsville, fell from a tree, July 1, fracturing several ribs and the clavicle.

PENNSYLVANIA.

Philadelphia.

Bequest.—By the will of Henry Cramer, who died July 28, the German Hospital receives the sum of $500.

Births Exceed Deaths.—During July 2,582 deaths were reported and 2,902 births. The births, therefore, exceeded the deaths by 320.

Milk Inspection.—The number of inspections made in July were 4,928, and 122,665 quarts were inspected. Of this number 1,540 quarts were condemned; 1,332 chemical examinations were made, and 502 microscopic examinations.

Bacteriologic Laboratory Report.—The report of the bacteriologic laboratory for July shows that 1,526 specimens were examined for diphtheria; 416 examinations were made of typhoid fever blood; 474 examinations of milk, and 74 of sputum. The laboratory supplied 598 bottles of antitoxin.

To Fight Typhoid.—There being no sign of diminution in the spread of typhoid fever in this city, the Bureau of Health has prepared a circular containing valuable instructions in regard to preventing the disease. Copies will be distributed by the assistant medical inspectors in a house-to-house visitation throughout the city.

Medical Inspection.—The number of inspections made by the medical inspectors, excluding schools, during the month of July aggregated 14,477. They ordered 414 fumigations, and examined 28 cases for special diagnosis; 164 cultures were taken, 74 injections of antitoxin made, and 980 vaccinations performed.

Violation of Pure Food Laws.—By the action of Dairy and Food Commissioner Warren a number of dealers were held under $400 bail each for court, and two defendants were fined $57.50 each, charged with selling drinks adulterated with saccharin. Warrants have been issued for several dealers, and still others are being watched by the agents of the commission.

Suits Against Meat Dealers.—On August 9 the semi-official announcement was made at the State Dairy and Food Bureau that within the next thirty days fifty or more suits will be brought against meat dealers in central Pennsylvania for selling "doctored" meats. Among the offenders are several agents of western companies. These suits will be brought in about twenty-five counties.

To and from Europe.—Dr. and Mrs. George E. Levis sailed on the *Caronia* from New York, August 8.——Dr. Walter M. L. Ziegler has returned from Europe.——Dr. Robert C. Moon, vice-consul for Liberia, has returned from Europe.——Dr. and Mrs. William B. Van Lennep returned August 8 from abroad.——Drs. V. S. Gaggin, William R. Gieser and M. P. O'Neill sailed on August 12 on the *Merion*.

Irreparable Fire Loss.—The Medical Hall of the University of Pennsylvania, Philadelphia, containing one of the most valuable anatomic collections in the world, was burned August 14. Very few of the specimens were saved. The loss on the building and exhibits is estimated at $150,000, but the anatomic collection can not be replaced. The fire occasioned a panic in the hospital adjoining the medical hall but no casualties occurred.

Hospital Reports.—During July there were admitted to St. Mary's Hospital 234 patients; remaining from last month, 90; discharged during July, 224; total number of patients in hospital, 100; charity patients, 288; pay patients, 36; ambulance calls, 62; brought by patrol, 45. Out-patient department—Brought by patrol, 84; new cases, 775; old cases, 1,659; *x*-ray treatments, 47; radiographs, 8; fluoroscope examinations, 9; total, 2,498.

River Pollution.—On August 9 the report of Chief Medical Inspector Cairns on the pollution of the Schuylkill River was made public by Director Martin. The river and its tributaries were recently inspected by Dr. Cairns and Dr. Seneca Egbert from Reading down to the Fairmount Park. A body of nuisance inspectors have been sent to Manayunk, where the conditions are especially bad. A copy of the report was sent to Dr. Samuel G. Dixon, state health commissioner, who finds much encouragement in the willingness exhibited by the different municipalities along the Schuylkill River to co-operate with the health department in improving the conditions that have been found a menace to public health.

Health Report.—The deaths from all causes during the week ended August 12 aggregated 438. This is a decrease of 45 as compared with last week and a decrease of 3 as compared with the corresponding week of last year. The principal causes of death were: Typhoid fever, 14; whooping cough, 5; diphtheria, 5; tuberculosis, 41; cancer, 14; apoplexy, 16; heart disease, 21; acute respiratory disease, 25; enteritis under 2 years, 83; Bright's disease, 30; premature birth, 11; congenital debility, 11; old age, 8; accidental injuries, 16, and marasmus, over 3 months, 17. There were 162 cases of contagious disease reported, with 19 deaths, as compared with 166 cases and 12 deaths reported the preceding week. There were 109 new cases of typhoid fever, an increase of 9 over last week.

GENERAL.

Missouri Valley Society to Meet.—The eighteenth annual meeting of the Medical Society of the Missouri Valley will be held at Council Bluffs, Iowa, August 24-25. The sessions will be held in the auditorium at Lake Manawa, a summer resort near the city. The president is Dr. S. G. Burnett, Kansas City, and the secretary, Dr. Charles Wood Fassett, St. Joseph, Mo.

American Surgeons Receive Degrees.—At the fourth centenary of the Royal College of Surgeons of Edinburgh, July 22, the honorary fellowship of the college was conferred on Drs. William S. Halsted, Baltimore; William W. Keen, Philadelphia; Howard A. Kelly, Baltimore; and *in absentia* Drs. William J. Mayo, Rochester, Minn.; Charles McBurney, New York, and John Collins Warren, Boston.

Death Rates in Large Cities.—The Bulletin of the Chicago Department of Health gives the following statistics of July mortality in cities of more than a half-million inhabitants:

Cities.	Population.	Deaths.	Rate.
New York	3,902,097	7,548	22.76
Chicago	1,990,750	2,280	13.48
Philadelphia	1,417,062	2,582	21.45
St. Louis	636,973	887	16.39
Boston	617,102	1,086	20.70
Baltimore	546,217	1,163	25.05

Chinese Immigration Frauds.—It is reported that Chinese immigrants are using solutions of adrenalin to conceal symptoms of trachoma. This practice is not original with the Chinese, as immigrants from Europe were found to be using this drug for the same purpose (The Journal, Dec, 17, 1904). It is reported that an American physician, engaged in private practice in Hong Kong, makes a specialty of putting Chinese into condition to pass the immigrant inspectors at San Francisco. The Public Health and Marine-Hospital Service is reported to have the matter under investigation.

THE YELLOW FEVER SITUATION.

INFECTION BELIEVED UNDER CONTROL—RELATIVELY LOW DEATH RATE—OUTSIDE COMMUNITIES STILL PANICKY.

Louisiana.

Steamer Held.—The Norwegian steamer *Saphir*, from Colon, is held at Quarantine, and two patients were taken off the ship and placed in the detention camp at the quarantine station.

Immune Attacked.—Surgeon Thomas D. Berry, United States Public Health and Marine-Hospital Service, one of the first to reach New Orleans, and considered to be immune, was stricken down with yellow fever August 10 and has been removed to the special yellow fever ward in Touro Infirmary.

Spread of the Fever.—Up to August 15, 1,122 cases have been reported in New Orleans, with 184 deaths, from 229 foci of infection. On August 15, 62 cases were reported, with 6 deaths, from 19 new foci. Outside of New Orleans there have been up to date 129 cases and 24 deaths.

Disinfection Day.—Next Sunday has been designated as a day of general disinfection for New Orleans, and appeals have been made to every householder, every boarding or lodging-house keeper, every hotel-keeper, every merchant and manufacturer, and every person having any enclosure of any nature, whether it be a stable or a room in an office building, to fumigate at 10 o'clock on that day, burning sulphur under direction of the Marine-Hospital officials, for at least two hours.

Failed to Screen Cisterns.—Hundreds of affidavits were filed in the courts August 15 against New Orleans property holders, under the new mosquito law, because they have failed to screen cisterns. The cases are disposed of promptly and without favor, each offender being fined $25 and costs.

Now Under Control.—Dr. Joseph H. White, United States Public Health and Marine-Hospital Service, declared on August 15, after revising the official record of the day, that "Yellow fever in New Orleans is now under control. In my judgment the disease will be stamped out with a fight to prevent the spread of infection. There will be other cases, but we now have the situation in hand."

Expert Arrives.—Dr. John Guiteras, the yellow fever expert, arrived in New Orleans August 15, and after a conference with Dr. White and inspections of the original infected district, he declares that the present methods will stamp fever out of New Orleans within forty days.

Would Force Relaxation of Quarantine.—The State Board of Health on August 8 decided to ask the governor to employ the national guard in enforcing some relaxation of the most drastic of the local quarantines in the state. Towns were ordered not to refuse admission to any person having a proper certificate of health not over twenty-four hours nor to any person having undergone six days' detention. Interference with trains and boats is forbidden, and mail, express and freight carried in fumigated cars must be admitted.

Baton Rouge has its local company of state militia acting as quarantine guards.——It is reported that a mass meeting of citizens has voted that there is no foundation for the conclusion that mosquitoes carry yellow fever, and that thereon the medical members of the board of health resigned.

Monroe.—The mayor of Monroe on August 15 called out a company of militia to support a shotgun quarantine established by citizens of Monroe, who objected to the order of the local health board, lightening the quarantine.

Shreveport has had six cases at its detention camp, but no deaths, and Texas has raised the quarantine against freight trains from Shreveport.——Shreveport has a new board of health, the old one having resigned. The new members are Drs. T. Edgar Schumpert, Milton F. Smith and Francis S. Furman, Mr. W. A. Mabry and Mr. Henry Bodenheimer.

St. John.—Quarantine guards at St. John are said to have beaten Judge J. L. Gaudet of that place when he wished to reenter on his return from Jefferson.——In the same place a woman and child are alleged to have been manacled and taken to an unfit camp.

Vinton.—The postoffice at Vinton has been closed until train service is resumed.

Outside Cases.—Two cases of yellow fever are officially reported at Tallulah.——On August 14 a case was found at Lutcher.——At Diamond and Goodhope plantations one suspicious and three positive cases were discovered.——Two more cases were discovered on the Wildwoods plantation in Jefferson Parish. Another case has developed at Port Barrow, Ascension Parish. Two cases have occurred in La Fourche Parish. Two cases and one death are reported at Porte Celeste, Plaquemine Parish.——A new focus of infection has been found at Lafayette.——At Patterson three new cases de- established.——A suspicious case was reported August 15 veloped, making 49 in all, and an emergency hospital has been from Algiers.——The one case at Alexandria has been succeeded by no more.

Other States.

Alabama.—A dissension has arisen between Dr. William H. Sanders, state health officer, Montgomery, and the governor of the state, in an attempt to fix the responsibility for the delay of four days which occurred before the executive approval of the quarantine order against Louisiana was secured.——A case of yellow fever appeared in Montgomery and, at the request of the Jefferson County Medical Society, Birmingham declared a quarantine against Montgomery, arousing active discussion. Dr. Sanders appeared before the Jefferson County Medical Society, Birmingham, and asked that the quarantine against Montgomery be lifted, as the one imported case there had been properly isolated and was recovering, and there were no other cases. By a vote of 39 to 13 it was ordered to recommend that the quarantine stand, because there was not absolute proof [illegible] case came from outside infection. The [illegible] the city authorities to wage a war of [illegible] mosquitoes.——The one yellow fever patient at Montgomery has recovered and without spread of infection.

Arkansas.—Legislative neglect is making trouble in the state, as the last legislature failed to appropriate anything for the State Board of Health, not even making any allowance for the salary of the secretary. Notwithstanding this the state has declared a complete quarantine against all infective places, leaving the execution of its orders to the national guard. No one who has left an infected point can be admitted to the state until five days thereafter. Tropical fruits and household goods from infected districts will not be admitted. These rules were formulated by the State Board of Health, of which Dr. George M. B. Cantrell, *Little Rock*, is president.——At rifle muzzle Helena refused a river boat permission to take on coal or lower a yawl.——Little Rock requires certificates of health from all who come from the South, and is engaged in oiling ponds and cleaning up the city.——Jonesboro has enforced its quarantine with the local company of national guard.

Georgia.—Savannah has declared a quarantine against persons and personal baggage coming from Louisiana. None from such points will be admitted until six days after departure therefrom.——Columbus has quarantined against all places where yellow fever exists or may exist, requiring those from infected points to undergo twenty days' detention.——Atlanta has in force a train inspection service to look for suspicious cases of illness and to learn where passengers have come from and their destination.

Kentucky.—Louisville has medical inspectors board all trains from the South looking for suspicious cases of illness. A screened ambulance and screened hospital ward are kept in readiness.——Kentucky, while open to refugees, requires transportation officials to report to the State Board of Health every case without a health certificate, thus enabling local supervision of every suspicious case. The board urged screening against mosquitoes and other disease-bearing insects, together with destruction of their breeding-places.——Fulton and Wickliffe have declared quarantines against infected points, but the State Board of Health ordered the quarantine raised, and advised the authorities at Paducah that its proposed quarantine would not be recognized, thus leading to the abandonment of the project. The state board said: "Local quarantines are worse than useless, giving rise to a false sense of security which interferes with the exercise of effectual precautions, and imposing unnecessary restrictions on travel and commerce. . . . No refugee is a source of danger unless he develops the disease, and not then if placed in a well-screened room and protected from mosquitoes." Paducah very sensibly set to work oiling stagnant water and cutting weeds that shelter mosquitoes.

Illinois.—It is reported from Cairo that the stegomyia fascia is more prevalent than last year.——The secretary of the State Board of Health believes extraordinary precautions will be necessary to prevent the fever from getting a foothold in southern Illinois. Past experience has shown that in previous epidemics the disease has remained almost dormant during the summer, but has broken out with fury in September and October.——Every passenger and freight train and boat coming from the South is carefully inspected at Cairo, Thebes or Brookport. Day and night watchmen are stationed on the railroad bridge at Cairo and the entire water front is patroled day and night. This rigidity of inspection will not be relaxed until the coming of frost.

Indiana.—It was reported August 15 that a mild case of yellow fever had appeared in Waterford, LaPorte County. The patient had recently returned from Louisiana, where she had helped to nurse two sisters who died from the disease—— The health officer at Crawfordsville telegraphed August 15 to the State Board of Health that a case resembling yellow fever had developed there. The state health authorities have sent Dr. Alembert W. Brayton, Indianapolis, to investigate this case.

Mississippi.—Cases have been reported at Sumrall and Lumberton.——Laurel, Ormisburg, Pervis and Aberdeen "will not admit passengers or baggage from any point on the map."—— Vicksburg has applied oil to all stagnant waters and lime to noisome spots.——Surgeon S. B. Young, United States Public Health and Marine-Hospital Service, addressed the city council and citizens of Jackson August 1, giving convincing arguments of the truth of the mosquito theory of transmission of yellow fever.——The health officer of Greenville, Dr. O. H. Stone, resigned on August 2, supposedly on account of friction with the city administration regarding quarantine.

New York.—One of the crew of the *Advance*, which arrived on August 3, died in quarantine of yellow fever. The record to date, out of more than 200 suspects, shows three genuine yellow fever cases, two of which were fatal. There were, on August 12, 19 members of ships' crews and passengers at Swinburne Island awaiting developments.

North Carolina.—Wilmington has the quarantine epidemic and refuses to admit persons or baggage from infected districts until they have undergone 15 days' detention.

Tennessee.—Chattanooga, Hamilton County and West Tennessee are quarantined against the infected region; Knoxville welcomes refugees.——Memphis, beginning August 7, enforced rigid quarantine against tropical fruits.——Coffeeville refuses to admit passengers or freight and express matter from infected districts.——At Memphis there has been a disagreement as to the limits of authority of the city and county boards of health that has caused suburban residents some inconveniences at inspection stations.——Dyersburg refuses admission to persons, animals and freight of every character and kind coming from infected districts, and has established a ten-day detention period.

Texas.—Orange, on August 3, reported in detention nearly 100 travelers, including some women and children, while it could not offer adequate accommodations for that many men. ——The Gregg County health officer, Dr. W. D. Northcutt, on August 2 "declared quarantine in this county against all points."

General.

Mexico.—The Superior Board of Health of Mexico reports on August 2 only four cases of yellow fever in the entire republic—all at Vera Cruz.——Trains and boats from New Orleans and Panama are being watched.

FOREIGN.

Poisoning from Shellfish in Scotland.—Dr. A. K. Chalmers, medical officer of health for Glasgow, in a recent report to the town council, calls attention to the dangers of poisoning from shellfish. During past summers many cases of enteric fever have been traced to consumption of shellfish at seaside resorts. For example, in connection with the Lochgilphead cases of enteric fever of two years ago, the regular gatherers of shellfish at that place rejected such as were regarded by them as "sick" because they lay on the surface, while the visitors collected and ate these without hesitation, not knowing that the healthy mollusc of the species then implicated was to be found below the surface of the sand. Thus, while visitors sickened after consuming shellfish gathered on the spot, no cases were traceable among the consumers of those dispatched to Glasgow in the course of trade.

South African Medical Congress.—The seventh South African Medical Congress was held at Maritzburg, June 12-17. Over seventy medical men were present, a record attendance, as in the majority of cases as great sacrifice of time and money was involved as for physicians in this country to attend the Portland session of the American Medical Association. The address of welcome was delivered by the governor of Natal. The *Natal Mercury*, kindly sent us by Dr. W. A. Backenstoe, states that Dr. Hyslop, in his presidential address, laid emphasis on the necessity for uniformity in the compilation of vital statistics and for uniformity in medical laws throughout the various South African colonies. A discussion took place on the report of a committee appointed at the last congress to consider the subject of forming a South African Medical Guild as a center for medical organization for all matters other than scientific work. The principle of a guild was adopted, but later a proposal definitely to instruct the committee to carry the principle into effect was dropped and it is understood that those interested in the subject will move on their own responsibility. The feeling that some such organization is urgently needed is universal, and although a strong party maintains that the work could be done by the branches of the British Medical Association, an insuperable obstacle to this lies in the objection of the practitioners in the Transvaal and the Orange River Colony to establish branches; while unless an organization extends over all the colonies it would be of little use.

Correspondence

Compensation of Physicians as Expert Witnesses.

CHICAGO, Aug. 11, 1905.

To the Editor:—In THE JOURNAL, Aug. 5, 1905, page 420, reference is made to the Nebraska case of Main vs. Sherman County, where it was decided, as has often been done in similar cases, that "one testifying as an expert on a subject requiring special knowledge and skill, in the absence of a special contract is entitled only to the statutory fee." The details of this particular case are unknown to me, but I do know that often the physician's testimony and advice constitute the determining factor in many law suits. I know also, by personal experience, that only too often such assistance is forgotten as soon as a favorable decision is rendered, and that even a moderate compensation for his services is refused. In order that the profession may not continue to be ruthlessly mulcted and shamefully imposed on, I beg to direct attention to the decision of the Appellate Court of the First District of Illinois, filed Dec. 23, 1898, in my case against Emlen S. Blye, where the judgment of the Circuit Court is reversed and the cause remanded. The details of this case were presented by me to the Illinois State Medical Society at its Galesburg meeting, May 18, 1898, and are published in the official transaction of the society for that year, as well in the *Medical Record*, Aug. 27, 1898. The result of my contention, which extended over nine years, conserves to some extent the rights of expert witnesses. It determines that if a physician, at the request of a party to a suit, performs any extra service for such party in the prosecution of the suit, a contract for compensation for such services is a valid one, and a recovery can be had thereunder. The point as to the legality of contract for extra compensation beyond the statutory witness fee, for the mere giving of expert testimony, was not raised. It is possible the Dixon decision has definitely settled that question. As an expert always renders some service beyond that of merely testifying, in the way of counseling with attorneys, if not otherwise, the probability is that the effect of the Dixon decision is nullified. In any event, members of the profession are now protected against those who would accept the benefit of their services and then repudiate the contract under which these services are rendered, provided only the contract to be for more than the naked testimony.

When called as an expert witness, therefore, the physician in most instances may confess his inability to answer satisfactorily the hypothetical question without an examination of the patient, which must be paid for. As the court expressly said in the well-known Dixon case: "A physician can not be punished for a contempt for refusing to make a postmortem examination, unless paid therefor, nor can he be required to prepare himself in advance for testifying in court by making an examination, or performing an operation, or resorting to a certain amount of study, without being paid therefor." I am anxious that the rights of tne physician in these cases should be understood. I received nothing in my case but my experience, for the patient went into bankruptcy about the time the decision was rendered in my favor. Nevertheless, it gives me much satisfaction to say that my legal fight of nine years established a principle which the profession is entitled to take advantage of and which, I trust, will tend to prevent further injustice and imposition.

Denslow Lewis.

Association News

Biographical Card Index and American Medical Directory.

In accordance with the decision of the House of Delegates at the Portland session, the American Medical Association is accumulating data for a biographical index of the medical profession of the United States, and also material for the American Medical Directory, which will shortly be issued. The assistance and co-operation of physicians is requested in this effort to publish a reliable directory of our profession without any suggestion of commercialism. In this connection we desire to call attention to advertising page 61. We hope that every reader of The Journal will give this matter his immediate attention.

Marriages

E. P. Brown, M.D., to Miss May Belle Hill, both of Bessemer, Ala.

Dickinson Gorsuch, M.D., to Miss Irene Evans, both of Baltimore, August 9.

J. Boyd Swonger, M.D., to Miss Mabel Broome, both of Voth, Texas, July 31.

W. E. Pugh, M.D., to Miss Austin, both of Miami, Fla., at DeLand, Fla., July 31.

William H. Lence, M.D., Jonesboro, Ill., to Miss Mary Alden of Anna, Ill., August 2.

Carl S. Wasseweiler, M.D., to Miss Edith Dunold, both of Milwaukee, in Chicago, July 17.

Ernest S. Mattox, M.D., Terre Haute, Ind., to Miss Emma Meseke of Seymour, Ind., August 3.

Hubert D. Brennan, M.D., Bristol, Conn., to Miss Celia Fanning of Hartford, Conn., August 2.

D. Nicola Golino, M.D., Providence, R. I., to Miss Carlotta Menente of Italy, at Boston, August 1.

John H. Doyle, M.D., Grafton, W. Va., to Annie C. Greany, M.D., of Fall River, Mass., August 10.

Homer F. Parr, M.D., Magdalena, Mexico, to Miss Maude Hitchcock of Wellington, Kan., June 28.

Hartzell Langstaff, M.D., Roberts, Ill., to Miss Martha J. Shute of Melvin, Ill., at Chicago, July 8.

James Cleland, M.D., Jr., to Miss Anna Estelle Siebert, both of Detroit, at New York City, July 31.

William Pitt Hall, M.D., Frankfort, N. Y., to Miss Susie Marie Douglass of Earlville, N. Y., July 26.

Bernard N. McLaffery, M.D., to Mayme Jeffries, M.D., both of Portland, Ore., at Ogden, Utah, July 26.

Frank R. Strong, M.D., Syracuse, N. Y., to Miss Hallie Gerdeane Morgan of Earlville, N. Y., August 2.

Richard J. Dowdall, M.D., to Miss Katherine Johnson, both of Crescent City, Cal., at San Francisco, August 3.

William Crozier Fawcett, M.D., Starkweather, N. D., to Miss Frances Edith Maywood of Toronto, August 1.

Luther Peck, M.D., Plymouth, Mich., to Miss Jeanne Thompson of Rochester, N. Y., at Union Lake, Mich.

Louis Smirnow, M.D., Bridgeport, Conn., to Miss Mabel A. Munn of Botsford, Conn., at New York City, February 17.

Walter Vernon Brem, M.D., Charlotte, N. C., to Miss Marion Wolcott Winkler of Milwaukee, at Pine Lake, Wis., August 3.

Deaths

L. J. Frazee, M.D. Medical Department of the University of Louisville, 1841, for many years a member of the faculty of his Alma Mater and of the Kentucky School of Medicine, and in his day one of the leading physicians, medical teachers and writers of his city, but for many years retired from practice and devoted to industrial and literary pursuits, died at his home in Louisville from senile debility, Aug. 12, 1905, aged 86.

Joseph Samuel Demaree, M.D. Memphis (Tenn.) Hospital Medical College, 1898, of Frankfort, Ky., a member of the state and county medical societies, died at the home of his father, near Bagdad, Ky., August 4, from typhoid fever, after an illness of five weeks, aged 38. At a meeting of the Franklin County Medical Society, August 5, resolutions of eulogy and regret were adopted.

Robert Fowler Beattie, M.D. McGill University Medical Department, Montreal, 1897, Brookline, Mass., a member of the Massachusetts Medical Society, was drowned off Phillips Beach, Swampscott, August 6, while taking his morning plunge, aged 35. For several years he served as ship's surgeon on the Cunard and Dominion lines.

Thomas J. Mitchell, M.D. University of Louisville (Ky.) Medical Department, 1848, surgeon of the One Hundred and Seventh Illinois Volunteer Infantry in the Civil War, and a prisoner in Libby Prison, died at his home in Bement, Ill., August 3, from dropsy, after an illness of more than a year, aged 82.

Horace Laidlaw, M.D. University of California Medical Department, San Francisco, 1880, chief surgeon of the Oceanic Steamship Company for five years, and surgeon to the Spreckels plantations at Maui, Hawaii, for three years, died at his home in San Francisco, August 2, after a long illness, aged 45.

Robert Edwin Jameson, M.D. Harvard University Medical School, Boston, Mass.. 1861, assistant surgeon and surgeon to the Eleventh Massachusetts Volunteer Infantry during the Civil War, died at his home in Jamaica Plain, Boston, August 4, from acute gastritis, after an illness of three hours, aged 67.

Orange H. Adams, M.D. Dartmouth Medical School, Hanover, N. H., 1884, a member of the American Medical Association, prominent in the medical and municipal life of Vineland, N. J., died at his home in that place, from spinal paralysis, August 6, after an illness of one week, aged 49.

Frank B. Donnelly, M.D. New York University, New York City, 1893, ill with tuberculosis, and discharged from the Rhode Island Hospital as incurable, committed suicide by shooting himself, in his office in Providence, R. I., while despondent, August 3, aged 42.

Robert Maitland Petrie, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1869, in 1872 and 1874 city physician of Jersey City, N. J., died suddenly at his home in Jersey City, August 3, from heart disease, aged 54.

John Gilman Pike, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1847, one of the oldest practitioners of Strafford County, N. H., died at his home in Dover, July 31, after a long period of feeble health, aged 87.

Merritt E. Graham, M.D. Michigan, 1878, of Rochester, N. Y., for nine years coroner of Monroe County, died at the Graham Sanatorium, Rochester, August 3, from disease of the stomach, after an illness of three years, aged 49.

E. G. Martin, M.D. University of Louisville Medical Department, 1905, of Rocky Hill, Ky., died at Glasgow, Ky., July 21, from the effects of an overdose of morphin, taken, it is supposed, with suicidal intent.

John W. Morrow, M.D. Jefferson Medical College, Philadelphia, 1872, said to be the oldest practitioner in Forest County, Pa., died at his home in Tionesta, August 5, after an illness of several years, aged 68.

Dowdell Wood Allen, M.D. Medical Department of the University of Tennessee, Nashville, 1905, died at his home in Winona, Texas, May 25, from typhoid fever, after an illness of 32 days, aged 23.

Julius C. Bowen, M.D. Jefferson Medical College, Philadelphia, 1856, major-surgeon of the Second Iowa Volunteer Cavalry in the Civil War, died at his home in Rochester, N. Y., August 2, aged 74.

Seth D. Boggs, M.D. Bellevue Hospital Medical College, New York City, 1886, died suddenly while being carried into his house in Brooklyn, N. Y., August 10, from heart disease, aged 53.

William Ray Bramlett, M.D. University of Louisville (Ky.) Medical Department, 1881, died at his home in Florence, Ala., August 2, from septicemia, after an illness of two months, aged 43.

John C. Coats, M.D. Vanderbilt University Medical Department, Nashville, Tenn., 1878, died at his home in Huntsville, Ala., July 30, after an illness of only three days, from typhoid fever.

Frederick Brittin, M.D. College of Physicians and Surgeons of Chicago, 1904, of Divernon, Ill., died at the home of his parents in Springfield, Ill., from septicemia, July 31.

Orville A. Harding, M.D. Rush Medical College, Chicago, of Chicago, was drowned while hunting, in the Flambeau River, near Ladysmith, Wis., August 11, aged 35.

Joseph W. Kumpe, M.D. Medical College of Alabama, Mobile, 1873, died at his home in White Sulphur Springs, Mont., August 4, after a lingering illness, aged 58.

Daniel R. Crow, M.D. Memphis (Tenn.) Hospital Medical College, 1891, died at his home in Lay, Miss., August 2, from heart disease, after a long illness.

Louis A. Hortubise, M.D. Laval University Medical Department, Quebec, 1894, died at his home in Lowell, Mass., August 5, after a long illness, aged 33.

William R. Nevin, M.D. New York, 1887, died at his home in Jersey City, N. J., from cirrhosis of the liver, August 2, after a long illness, aged 45.

James Parker, M.D. Trinity Medical College, Toronto, Ont., 1871, died at his home in Ballard, Wash., August 2, from heart disease, aged 63.

David L. Deyo, M.D. Missouri, 1869, of Louisiana, Mo., died at St. Elizabeth's Hospital, Belleville, Ill,. August 1, aged 79.

Philip Fischer, M.D. University of Würzburg, Germany, 1868, died at his home in Cincinnati, August 9, aged 60.

Book Notice

The Pharmacopeia of the United States of America, By Authority of the United States Pharmacopeial Convention held at Washington, 1900. Eighth Decennial Revision. Revised by the Committee of Revision and published by the Board of Trustees. Official from Sept. 1. 1905. Cloth. Pp. 692. Price, $2.50. Philadelphia: P. Blakiston's Son & Co.

After five years' labor the revision of the Pharmacopeia of the United States has been effected and the work appears in a stately volume of 700 pages. Following precedent, 70 pages are devoted to a historical introduction, abstract of the proceedings of the national convention for revising the Pharmacopeia, with a list of the delegates from the various medical and pharmaceutical bodies and of the federal medical service represented, preface and introductory notices giving general directions for physical constants and standards, general processes and operations and a number of lists, i. e., of articles added, articles dismissed, changes in official Latin and English titles and comparative table showing the strength of the more important pharmacopeial substances and preparations in the preceding and the present Pharmacopeia. Then follows the text of the official articles, comprising over 500 pages, with the definitions in large, clear type and the tests in smaller print. While many new articles have been added, the number has not been increased, since an equal number of articles has been dismissed. The principal additions comprise twenty synthetical chemicals, an equal number of natural or synthetic principles representing the volatile oils, the suprarenal and thyroid glands, antidiphtheritic serum, a number of fluid extracts, several elixirs, emulsions, solutions, oleats, ointments, tinctures and effervescent salts. The dismissals are represented largely by drugs more or less obsolete and their respective extractive preparations, a number of pharmaceutical preparations superseded by more eligible and definite preparations and certain salts inorganic and organic now, but little used. The principal changes are represented by the change in titles of some chemicals, such as the acids of arsenic and chromium to arseni trioxidum and chromii trioxidum respectively, from carbolic acid to phenol, and chloral to chloral hydratum, the latter to conform to their chemical character. The chemical nomenclature has been retained in preference to that adopted by the American Association for Advancement of Science; in which the final "e" is deleted in the halogens and alkaloids. The pharmacopeial usage in distinguishing between alkaloids and glucosids by omitting the final "e" in the latter seems too popular to give way to the continental method adopted by the American Chemical Society. An innovation is the so-called purity rubric, which appears as a short definition at the head of all definite chemical compounds through which the minimum degree of purity of the articles is limited, thus: Potassium iodid KI 164.76. "It should contain not less than 99 per cent. of pure potassium iodid, and should be kept in well-stopped bottles." This allows not to exceed 1 per cent. unavoidable innocuous impurities, which are strictly limited in the nearly solid page of fine print giving tests and reactions, by which the merest trace of noxious impurities, heavy metals, etc., are absolutely excluded. In this respect the work is believed to be the most complete of any pharmacopeia and satisfactory from a pharmaceutical standpoint. While the changes in the strengths of articles, particularly galenicals, are not numerous, yet they are important, since the principles of standardizing drugs and their preparations has been extended to some sixteen drugs and many of their preparations. The most important change of all, however, at least from the physician's standpoint, is the change in the strength of some of the tinctures. In conformity with requirements of the International Conference for the Unification of Potent Medicines of 1902, the tinctures, except the compound ones, have been put in two groups: (1) Tincture of potent drugs to be 10 per cent. drug strength; and (2) of non-potent drugs 20 per cent. drug strength. Thus the 15 per cent. tinctures, including most of the so-called narcotic drugs, have been discarded for the 10 per cent. strength, and are, therefore, one-third weaker. The two largely used tinctures, aconite and veratrum viride, 35 and 40 per cent. drug strength respectively, have thus been reduced to the 10 per cent. strength. This is of the greatest importance to physicians and should have the widest publicity so that the fact may be generally recognized by September 1, when the new Pharmacopeia goes into effect—becomes official. Another innovation is the introduction of the average doses expressed in metric and customary weights and measures. This is not intended as a limitation on the physician, but simply an attempt to furnish some sort of official or authoritative standard for reference to pharmacists, especially as a guide in compounding and dispensing prescriptions. In order to avoid conflict with federal, and especially state, laws regulating standards for articles of food, it is especially announced in the preface that the standards of the United States Pharmacopeia are designed for and apply only to the articles for medicinal uses as distinguished from their employment as foods or in technical and industrial uses. The usual appendix of reagents and a valuable collection of tables for reference completes the volume, which, barring some minor deficiencies, is certainly the most elaborate pharmacopeia yet devised for any country.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries *for* this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

LIFE AND HABITS OF THE MOSQUITO.

Whitewright, Texas, Aug. 6, 1905.

To the Editor:—Please inform me where I can procure a recent work on the anatomy, habits and habitat of the various species of the mosquito

S. H. Landrum, M.D.

Answer.—Our correspondent is one of many who ask the same question. "The Mosquito," by Howard, cloth, $1.50, is a good book.

An excellent article on the subject, by Dr. John R. Taylor, Havana, Cuba, was published in The Journal, July 8, 1905, page 90. The best information is to be had in the bulletins of the United States Public Health and Marine-Hospital Service, which may be had by addressing the surgeon general, Dr. Walter Wyman, Washington, D. C.

INTERNATIONAL MEDICAL CONGRESS.

McKeesport, Pa., Aug. 9, 1905.

To the Editor:—Will you kindly inform me of the date of the meeting of the International Medical Congress in Lisbon next year? T. L.

Answer.—The International Medical Congress will meet April 19 to 26, 1906. The date and the program are given in The Journal, July 29, p. 337. Other information is in July 22, p. 262 (report of American Committee), June 17, pp. 1941 (excursion announcement) and 1942, and in Vol. xliv, pp. 139, 881, 1046, 1129 and 1140.

PHYSICIANS' CARDS IN NEWSPAPERS.

Dr. L. sends us the cards of some physicians from local newspapers, and asks us if they are strictly ethical. In addition to the name, address and telephone numbers, one of these cards states that the advertiser is ' Surgeon to —— hospital, Surgeon to to —— railway. United States examining surgeon, etc." The other gives similar facts, and in addition states: "Glasses accurately fitted. Surgery, and diseases of women."

Answer.—The profession generally regards as reprehensible the advertisement in newspapers by physicians of anything more than name, address, office telephone numbers, and special branches to which practice is limited. The details of the interpretation of this general rule, however, are to be handled by the local county medical society. Our correspondent and others will be interested in referring back to what we have already said on this subject in The Journal, Aug. 13, 1904, p. 485; Oct. 3, 1904, p. 1073; and May 20, 1905, p. 1631.

DETERIORATION OF APOMORPHIN HYDROCHLORATE.

Columbus, Ga., Aug. 3, 1905.

To the Editor:—What chemical change takes place when apomorphin hydrochlorate changes color from age? Is this a deterioration, and is the resulting compound poisonous? M. C.

Answer.—This is so unstable a compound that the U. S. Pharmacopeia (1905) directs that it should be kept in small, dark, amber-colored vials which have been previously rinsed with diluted hydrochloric acid and dried. The compound of this alkaloid prepared artificially from morphin with HCl is so delicate that on exposure to light and air it acquires a greenish tint, showing decomposition. The exact nature of the chemical change is obscure. When discolored the article should not be used.

GERMAN MEDICAL JOURNALS AND DICTIONARIES.

Detroit, Mich., Aug. 5, 1905.

To the Editor:—The physicians, Drs. Chassell and Bush, who inquired for German-English dictionaries, etc., would undoubtedly appreciate the German and English dictionary edited by Frederick Treves and Hugo Lang, published by J. & A. Churchill, 11 Burlington Street, London, England. L. Breisacher.

State Boards of Registration

COMING EXAMINATIONS.

Wyoming State Board of Medical Examiners, State Capitol, Cheyenne, Wyo., September 6. Secretary, S. B. Miller, Laramie.

Massachusetts Board of Registration in Medicine, State House, Boston, September 12-13. Secretary, E. B. Harvey, Boston.

Index to State Board Reports.—Reports of other state board examinations which have been held this year have been published in The Journal as follows: February 11, page 488, Arizona January report. February 18, page 566, District of Columbia and Oregon January reports. February 25, page 646, Indiana, North Dakota, Rhode Island and South Dakota January reports. March 4, page 732, Wisconsin January report. March 11, page 810, Vermont February report. March 18, page 896, Illinois and Washington January reports, with the questions asked in Washington. April 1, page 1059, Kansas February report. April 15, page 1211, Maine March report, with the questions asked in Oklahoma at the examination held in March. April 22, page 1303, Connecticut March report, and Montana and North Dakota April reports. May 6, page 1467, Arkansas April report, Nebraska February report, Oklahoma March report, and Utah January and April reports. May 13, page 1553, Rhode Island and Minnesota April reports, with questions asked in Minnesota. May 20, page 162, California, Indian Territory, Idaho and Kentucky April reports, with questions asked in Kentucky. May 27, page 1699, Arizona and West Virginia April reports. June 3, page 1795, District of Columbia April report. June 17, page 1950, North Carolina May report, with list of questions asked. June 24, page 2001, Illinois April report and Louisiana May report. July 1, page 60, Illinois May report. July 8, page 125, Indiana May report. July 15, page 209, Kansas April report, Minnesota and Wyoming June reports, and questions asked at Pennsylvania June examination. July 29, page 344, New Jersey and Delaware June reports, and Utah July report. August 12, page 487, Arkansas July report and South Carolina June report.

Connecticut July Report.—Dr. Charles A. Tuttle, secretary of the Medical Examiners of the Connecticut Medical Society, reports the written examination, held at New Haven, July 11-12, 1905. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of persons examined was 27, of whom 23 passed and 4 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
Yale University, (1902) 80.1, (1904) 78.7,	(1905)	78.1, 80.1, 81.4, 81.8, 86.5.
University of Pennsylvania	(1901)	78.2
Tufts Med. Coll.	(1905)	75.6
College of P. and S., New York.. (1903) 84.2;	(1905)	82
Jefferson Med. Coll.	(1905)	77.2, 81.4
University of New York	(1880)	77.6
University of Vermont	(1901)	78.4
Baltimore Med. Coll.	(1905)	79.6
University of Maryland (1901) 78.1;	(1905)	82.3
College of P. and S., Boston	(1904)	75.6
College of P. and S., Baltimore	(1905) 76.2, 79.9	80.1
College of P. and S., Cleveland	(1905)	77.8
FAILED.		
Long Island College Hospital	(1896)	73.2
Maryland Med. Coll.	(1905)	60.7
University of Michigan	(1890)	72
Tufts Med. Coll.	(1905)	68.6

Illinois May Report.—Dr. J. A. Egan, secretary of the State Board of Health of Illinois, reports the written examination held at Chicago, May 3-5, 1905. The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 417, of whom 410 passed and 7 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
American Coll. of Med. & Surg. (1904) 75; (1905). The grades of 76 and 77 were reached by one each; 78 was reached by five; 79, by three; 80, by five; 81, by five; 83, by three; 84, by one; 85, by two; 86 by one; 87 by three; 89 and 90 by one each.		
Barnes Med. Coll	(1904)	78
Bellevue Hosp. Med. Coll	(1880)	1
Bennett Med. Coll. (1905). The grade of 78 was reached by one: 79, by four; 80, by one; 81, by two; 82, by three; 83, by four: 84, by four; 85, by one; 88, by 2.		
Cleveland Homeo. Med. Coll	(1905)	85, 86
College of Med. and Surg., Chicago (1904) 76;	(1905)	79, 81, 82, 91
College of P. & S., Chicago (1904) 78, 90 (1905). The grade of 77 was reached by one; 78, by four: 79, by three; 80, by five; 81, by nine; 82, by eighteen: 83, by fourteen; 84, by twenty-two; 85, by nineteen: 86, by sixteen; 87, by thirteen; 88, by nine; 89, by three; 90, by three; 92 and 95, by one each.		
Dearborn Med. Coll	(1905)	82, 85, 86, 86, 87, 86
Eclectic Med. Inst., Cincinnati (1885) 77;	(1905)	77
Hahnemann Med. Coll., Chicago (1905). The grade of 79 was reached by seven: 80, by three; 81, by four: 82, by eight; 83, by one; 84, by six; 85, by two; 86, 87, 88, by one each; 89, by two.		
Harvey Med. Coll	(1905)	81, 84, 88
Hering Med. Coll	(1905)	77, 80, 81, 82, 82, 82, 84, 86, 88
Illinois Med. Coll.	(1905)	77, 81, 82, 82, 83, 88
Jenner Med. Coll (1904) 82;	(1905)	76, 80, 80, 81, 83, 87
National Med. Univ., Chicago (1904) 85:	(1905)	75, 76, 77, 78, 80, 82.
Northwestern University (1905). The grades of 79, 81, 82 and 94 were reached by one each; 83 was reached by four; 84, by six; 85, by five; 86, by eight; 87, by five; 88, by nine; 89, by fourteen; 90, by eight; 91, by six; 92, by three; 93, by two.		
Rush Med. Coll. (1903) 82; (1904) 86, 87, 90, 90, 94 (1905). The grades of 81, 82 and 91 were reached by one each; 83 was reached by two; 84, by two; 85, by two; 86, by four; 87, by six; 88, by eight; 89, by five; 90, by three; 92, by three.		
Toledo Med. Coll	(1905)	82, 84, 85, 86, 86, 87
Western Med. Coll., London, Ont.	(1905)	84, 88
FAILED.		
College of Med. & Surg., Chicago	(1905)	73, 74
Illinois Med. Coll.	(1905)	65
Jenner Med. Coll	(1905)	71
Physio-Medical Coll., Indianapolis	(1887)	56

The general average attained by all representatives of the

American College of Medicine and Surgery who passed was 81.4; by representatives of Bennett Medical College, 82.2; of the College of Medicine and Surgery, Chicago, 81.8; of the College of Physicians and Surgeons, Chicago, 84.2; of Hahnemann Medical College, Chicago, 82.3; of Illinois Medical College, 82.1; of Jenner Medical College, 81.2; of National Medical University, 79; of Northwestern University, 87.6; of Rush Medical College, 88.3.

Maine July Report.—Dr. W. J. Maybury, secretary of the Maine Board of Registration of Medicine, reports the examination, partly oral and partly written, held at Augusta, July 11-12, 1905. The number of subjects examined in was 10; total number of questions asked, 100: percentage required to pass, 75. The number of individuals examined was 44, of whom 41 passed and 3 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Boston University,	(1904) 84.3, 89.8, 83.4; (1905)	80.1, 77.6
Medical School of Maine	(1905)	82.4, 75.5, 84.5, 86.6, 90.2, 82.8, 78.5, 81, 93.2, 84.6, 79.3, 87.6, 77.5, 87.4, 84.6, 80.7.
College of P. & S., Boston	(1905)	80.2, 81.4
Jefferson Med. Coll	(1905)	79.3, 86.9, 78.3
Johns Hopkins University	(1905)	88.5
Albany Med. Coll	(1905)	87.2
McGill University	(1899)	77.2
Columbia University	(1892) 75; (1899)	93.2
University of Vermont	(1905)	90.1, 78
Baltimore Med. Coll	(1905)	86 8
Woman's Med. Coll., Philadelphia	(1905)	87.1
Harvard University	(1905)	81.1, 93
Medico-Chirurgical Coll., Philadelphia	(1905)	92, 83.5
University of Pennsylvania	(1905)	80.3, 90.6

The general average attained by all representatives of the Medical School of Maine who passed was 83.5.

New Hampshire July Report.—Dr. H. C. Morrison, regent of the New Hampshire State Board, reports the written examination held at Concord, July 7-8, 1905. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 20, of whom 15 passed and 5 failed. The following colleges were represented:

PASSED.

Colleges.	Year Grad.	Per Cent.
Tufts Med. Coll.	(1902) 82;* (1905)	84
Dartmouth Med. Coll.	(1904) 76; (1905) 82, 87,	83
Harvard University	(1904) 82; (1905)	88
College of P. and S., New York	(1896) 80; (1905)	86
Jefferson Med. Coll.	(1905)	79
Detroit Coll. of Medicine	(1905)	77
McGill University	(1904)	81
Johns Hopkins University	(1904)	87
Maryland Med. Coll.	(1903)	75*

FAILED.

College.	Year Grad.	Per Cent.
Laval University	(1904) 61.5,* 73.8;* (1903)	62.1
Jefferson Med. Coll.	(1905)	73.9
Illinois Med. Coll.	(1902)	73.1

*Second Examination.

Ohio June Report.—Dr. T. Windero, secretary of the State Board of Medical Registration and Examination, reports the written examinations held at Columbus, Cleveland and Cincinnati, June 13-15, 1905. The total number of candidates examined was 192, of whom 188 passed and 4 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Miami Med. Coll. (1905). The grades of 94, 83 and 82 were reached by one each: 85, 84, 87, 80, 93, 90, 91 by two each; 88 was reached by three.		
Eclectic Med. Inst., Cincinnati (1881) 88; (1905). The grades of 77,* 83, 75, 85, 89 and 95 were reached by one each; 80 and 88 by two each.		
Pulte Med. Coll	(1905)	85, 85.91
Medical College of Ohio (1905). The grade of 85 was reached by four; 86, by two; 87, by five; 88, by two; 89, by three; 90, by three; 91, by one; 92, by two; 93, by four; 94, by two.		
Western Reserve Univ. (1905). The grades of 87, 89, 93 and 97 were reached by one each; the grade of 88 was reached by four; 90, by two; 91, by two; 92, by four; 96, by two. The grade attained by one individual is not stated.		
Cleveland Homeo. Med. Coll. (1904) 85; (1905) 88, 83, 89, 90, 90, 85, 79, 92, 81, 86.		
College of P. & S., Cleveland. The grades of 81, 82, 84, 87, 90, 95 and 96 were reached by one each; 89 was reached by three; 91, by two, and 92 by two.		
Ohio Med. University (1905). The grades of 81, 78, 85, 82, 92, 93 and 91 were reached by one each; 84 was reached by five; 86, by two; 87, by two; 88, by four; 89, by four; 90, by four.		
Starling Med. Coll. (1905). The grades of 76, 77, 78, 79, 80, 86, 88, and 89 were reached by one each; 75 was reached by two; 81, by four; 83, by three; 84, by three; 85, by three; 87, by two; 90, by two.		
Hahnemann Med. Coll., Philadelphia	(1905)	90
Leonard Med. Coll	(1905)	75
College of P. & S., New York	(1902)	92

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Aug. 12, 1905:

Skinner, George A., asst.-surgeon, left Fort Harrison, Mont., on practice march.

Moseley, E. B., deputy surgeon-general, left chief surgeon's office, Denver, on thirty days' leave of absence.

Yost, John D., asst.-surgeon, granted thirty days' leave of absence.

Bourke, James, asst.-surgeon, relieved from temporary duty at Fort McHenry, Md., and ordered to Fort Howard, Md., for temporary duty during the absence of Asst.-Surgeon Compton Wilson, on whose return to Fort Howard, Lieut. Bourke will return to duty at the Medical Supply Depot, New York City.

Kiersted, Henry S., asst.-surgeon, relieved from duty at Presidio of Monterey, Cal., and ordered to Fort St. Michael, Alaska, for duty.

Pierson, Robert H., asst.-surgeon, relieved from duty at Fort St. Michael, Alaska, and ordered to Fort Gibbon, Alaska, for duty.

Hathaway, L. M., asst.-surgeon, relieved from duty at Fort Gibbon, Alaska, and ordered to proceed to Seattle, Wash., and report by telegraph to the military secretary of the Army for further orders.

La Garde, Louis A., surgeon, leave of absence extended thirty days.

Bispham, William N., asst.-surgeon, in addition to his other duties at Fort Logan, Colo., is announced as temporarily in charge of chief surgeon's office, Department of Colorado, during the temporary absence on leave of Lieut-Col. Edward B. Moseley, deputy surgeon general.

Borden, William C., surgeon, granted thirty days' leave of absence about Aug. 8, 1905.

Smart, William M., asst.-surgeon, having reported arrival at Seattle, Wash., is assigned to duty at Fort Caswell, N. C.

Buck, C. D., asst.-surgeon, left with recruits from Jefferson Barracks, Mo., en route to Fort Walla Walla, Wash.

Marshall, John S., examining and supervising dental surgeon, relieved from duty at the Presidio of San Francisco, and assigned to duty at the Army General Hospital, Presidio of San Francisco.

Van Kirk, Harry H., contract surgeon, granted leave of absence for one month from Fort Sill, Okla.

Long, Charles J., dental surgeon, left Fort Yellowstone, Wyo., and arrived at Fort Lincoln, N. D., for duty.

George, William R. S., contract surgeon, arrived at New York City, and, having been relieved from duty in Porto Rico, proceeded to Fort Monroe, Va., for duty.

Vaughan, Milton, contract surgeon, left Fort Douglas, Utah, and arrived at Fort Crook, Neb., for duty.

Tukey, William H., contract surgeon, granted leave of absence for two months.

Warwick, Clarence A., contract surgeon, arrived at San Francisco, Cal., and availed himself of leave of absence for four months from the Philippines Division.

Brown, Wilmont E., contract surgeon, granted leave of absence for two months.

Suggs, Frank, contract surgeon, relieved from further duty in the Philippines Division, and ordered to duty at Fort Mansfield, R. I., at the expiration of his present sick leave of absence.

Slater, Ernest F., contract surgeon, returned from leave of absence to duty at Fort Hancock, N. J.

Clayton, George R., contract surgeon, ordered from Columbus Barracks, Ohio, to San Francisco, Cal., with recruits, and to proceed thence to the Philippines Division for duty.

Lauderdale, Clarence E., dental surgeon, granted leave of absence for one month.

Macy, Fred S., contract surgeon, returned to Allegheny Arsenal, Pa., from leave of absence.

Kieruiff, H. Newton, contract surgeon, relieved from duty in the Department of California, and ordered to duty in the Philippines Division.

Navy Changes.

Changes in the Medical Corps, U S. Navy, for the week ending Aug. 12, 1905:

Wise, J. C., medical director, orders of July 29, 1905, modified; ordered to report to the Surgeon-General of the Navy, Aug. 10, 1905, for duty in command of the Naval Medical School.

Boyd, J. C., medical director, ordered to additional duty as president of the Naval Examining Board, and Naval Medical Examining Board, Naval Medical School, Washington, D. C.

Sellers, F. E., asst.-surgeon, G. S. Hathaway, appointed asst.-surgeons, with rank of lieutenant (junior grade), from Aug. 1, 1905.

Spratling, L. W., surgeon, ordered to the Naval Station, New Orleans.

Taylor, J. L., asst.-surgeon, detached from the Naval Hospital, Pensacola, Fla., September 29, and ordered to Washington, D. C., October 2, for course of instruction at the Naval Medical School.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Aug. 9, 1905:

Irwin, Fairfax, surgeon, leave of absence for one month from Aug. 8, 1905, granted by Bureau letter of July 12, 1905, revoked.

Blue, Rupert, P. A. surgeon, to report at Washington, D. C., for special temporary duty.

Blue, Rupert, Currie, D. H., Greene, J. B., and McMullen, John, P. A. surgeons, and Rucker, W. C., Ebert, H. G., Smith, F. C., and Steger, E. M., asst.-surgeons, to proceed to New Orleans and to report to Surgeon J. H. White for special temporary duty.

Lavinder, C. H., [illegible] 'd to Fontainebleau, Miss., and assume [illegible] mp.

Stansfield, H. A., [illegible] from duty in the Canal Zone, and directed to proceed to New York and report arrival by wire.

Amesse, J. W., P. A. surgeon, to proceed to Cairo, Ill., and assume temporary command of the service.

Ashford, F. A., asst.-surgeon. Bureau order of August 7, directing to proceed to New Orleans revoked, and directed to proceed to Immigration Depot, New York, and report to Suregon G. W. Stoner for duty.

McKeon, F. H., asst.-surgeon, relieved from duty at U. S. Marine Hospital, New Orleans, and directed to report to Surgeon J. H. White for special temporary duty.

Sweet, E. A., Frost, W. H., and Mullan, E. H., asst.-surgeons, to proceed to New Orleans and report to Surgeon J. H. White for special temporary duty.

Frost, W. H., asst.-surgeon, to proceed to Norfolk, Va., and assume temporary charge of the service.

Olsen, E. T., asst.-surgeon, relieved from duty at Immigration Depot, New York, and directed to proceed to New York (Stapleton), and report to medical officer in command for duty and assignment to quarters.

Boyd, F., acting asst.-surgeon, granted leave of absence for thirty days from Aug. 1, 1905.

Hunter, S. B., acting asst.-surgeon, granted leave of absence for thirty days from Aug. 1, 1905.

Keatley, H. W., acting asst.-surgeon, granted leave of absence for two days from Aug. 6, 1905, under the provisions of Paragraph 210 of the Regulations.

Safford, M. V., acting asst.-surgeon, granted leave of absence for four days from Aug. 4, 1905, under the provisions of Paragraph 210 of the Regulations.

Stewart, W. J. S., acting asst.-surgeon, granted leave of absence for thirty days from Oct. 1, 1905.

Tarbell, B. C., acting asst.-surgeon, granted leave of absence for five days from Aug. 20, 1905.

Townsend, W., acting asst.-surgeon, granted leave of absence for five days from Aug. 7, 1905.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the period from July 29 to Aug. 5, 1905:

SMALLPOX—UNITED STATES.

California: Los Angeles, July 15-22, 2 cases.
Illinois: Chicago, July 22-27, 6 cases.
Louisiana: New Orleans, July 15-29, 1 case, 4 deaths.
Michigan: Grand Rapids, July 22-29, 5 cases.
Missouri: St. Joseph, July 15-22, 1 case.
Montana: Butte, July 16-23, 1 case.
New Hampshire: Nashua, July 15-22, 1 case.
Ohio: Cincinnati, July 21-28, 2 cases; Toledo, July 15-22, 6 cases.
Pennsylvania: York, July 22-29, 1 case.

SMALLPOX—FOREIGN.

Argentine: Buenos Ayres, April 1-30, 43 deaths.
France: Paris, July 8-15, 6 cases, 2 deaths; St. Etienne, June 1-30, 2 cases.
Great Britain: London, July 8-15, 1 case.
India: Bombay, June 27-July 4, 7 cases; Karachi, June 25-July 2, 2 cases; Madras, June 24-30, 2 cases.
Russia: Moscow, July 1-8, 11 cases, 20 deaths; Odessa, June 17-July 15, 26 cases, 3 deaths; St. Petersburg, July 1-8, 5 cases, 3 deaths.
Spain: Barcelona, July 10-20, 4 deaths.
Turkey: Constantinople, July 8-16, 5 deaths.

YELLOW FEVER—UNITED STATES

Louisiana: Morgan City, July 3, 1 case; Shreveport, Aug. 1, 1 case; New Orleans, July 21-Aug. 3, 308 cases, 59 deaths.
Mississippi: Gulf Quarantine, July 22-Aug. 3, 14 cases, 1 death; Lumberton, July 28, 1 case; Sumrall, Aug. 2, 1 case.

YELLOW FEVER—FOREIGN.

Brazil: Sao Paulo, June 15, 1 case.
Ecuador: Guayaquil, June 27-July 4, 2 deaths.
Guatemala: Livingston, July 8-15, 3 cases.
Honduras: Puerto Cortez, June 14-21, 2 deaths.
Mexico: Tierra Blanca, July 16-22, 1 case, 1 death; Vera Cruz, July 16-29, 2 cases.
Panama: Colon, July 10-17, 1 case; Panama, 9 cases, 3 deaths.

PLAGUE.

China: Hongkong, May 13-20, 20 cases, 18 deaths.
India: General, June 10-17, 5,413 cases, 4,883 deaths; Bombay, June 24-July 4, 58 deaths; Karachi, June 25-July 2, 34 cases, 34 deaths; Madras, June 24-30, 1 death.
Japan: Formosa, June 20-30, 39 cases, 40 deaths.
Peru: Callao, June 11-20, 1 case, 1 death; Lima, June 11-20, 3 cases, 1 death; Mollendo, June 11-20, 2 cases, 1 death; Payta, June 11-20, 2 cases, 1 death.
Straits Settlements: Singapore, June 10-17, 2 deaths.

CHOLERA.

India: Madras, June 24-30, 1 death.

MEDICAL SCHOOLS OF THE UNITED STATES

Below is given a brief description of every college in the United States that is legally chartered to confer the degree of doctor of medicine, and whose diploma is recognized by at least one state licensing board. The list includes the sectarian as well as the regular colleges, as their graduates are physicians in the eyes of the law. The information given is, as a rule, obtained from the catalogues and has been submitted to the dean of each school for his inspection and approval. Colleges which belong to the American or the Southern Medical College Association or other organization of colleges have requirements for admission of students according to the rules of these associations, unless their requirements are higher, in which case a statement is made to that effect. Extracts from these rules are given at the close of the list of colleges.

ALABAMA.

Alabama, population 1,828,697, has two medical colleges, the Medical College of Alabama and the Birmingham Medical College, located in Mobile and in Birmingham. The population of each city is over 38,000, and board and room may be obtained from $12 to $20 per month.

Birmingham.

BIRMINGHAM MEDICAL COLLEGE.—This school was incorporated in 1894 and is situated in Birmingham, a manufacturing town of 38,415. The clinical advantages are good. The Hillman, St. Vincent's, Pratt and County hospitals are accessible to the students. The laboratories are well equipped. There are 17 professors and 12 assistants, total 29. The school is a member of the Southern Medical College Association. The course of instruction embraces four separate sessions of six months each. The fees are $75 for each of the first three years and $105 for the fourth. The Dean is Dr. B. L. Wyman. Registration, 1904-5, 75, graduates, 16. Next session opens Oct. 3, 1905, and closes April 1, 1906.

Mobile.

MEDICAL COLLEGE OF ALABAMA.—This is the Medical Department of the University of Alabama, organized in 1859. The City Hospital furnishes free clinical material. The faculty consists of 8 professors and 12 lecturers, 20 in all. It is well equipped with building, laboratories, dispensary, etc. It is a member of the Southern Medical College Association. The course of study covers four years of six months each. The total fees for each of the first three years is $100; for the fourth year. $125. The Dean is Dr. George A. Ketchum. Total registration, 1904-5, 170; graduates, 41. The fortieth session will begin Oct. 1, 1905, and will close April 10, 1906.

ARKANSAS.

Arkansas, population 1,311,564, has one medical college, located in Little Rock. Board and lodging costs from $13 to $18 per month.

Little Rock.

UNIVERSITY OF ARKANSAS MEDICAL DEPARTMENT.—This college is located at Little Rock, population about 60,000. It was organized in 1879 as the Arkansas Industrial University Medical Department. Hospital facilities are furnished by Logan H. Roots Memorial Hospital, St. Vincent's Infirmary and Pulaski County Hospital, the latter having a capacity of 200 beds. The teaching body consists of 15 professors and 20 lecturers and assistants, total 35. Dr. F. L. French, Little Rock, is Secretary. The fees are: Matriculation $5, paid but once; annual fees $60, and graduation $25. Total number of students at last session, 220; graduates, 32. The next course of lectures begins Oct. 16, 1905, and ends April 14, 1906.

CALIFORNIA.

California, population 1,485,053, has eight medical colleges. Five are located in San Francisco, a city of about 400,000 inhabitants. They are Cooper Medical College, Medical Department of the University of California, California Medical College, Hahnemann Medical College of the Pacific, and the College of Physicians and Surgeons. The clinical facilities of San Francisco are good; board and lodging can be obtained for from $20 to $30 a month. The College of Medicine of the University of Southern California is situated in Los Angeles, population 102,479. Board and lodging can be obtained in that city for $4 a week and upward. The Oakland College of Medicine and Surgery is in Oakland.

Oakland.

OAKLAND COLLEGE OF MEDICINE AND SURGERY.—The fourth session of this school will begin Aug. 15, 1905, and end May 15, 1906. The length of the course has been changed from eight to nine months, beginning with the sessions of 1905-6. The Registrar is Dr. Edward N. Ewer. The faculty numbers 28. Tuition is about $115 yearly. There were 12 students last session, divided the first three years. There has not been a graduating class as yet.

San Francisco.

COOPER MEDICAL COLLEGE.—This school was organized in 1858, though its present name was not adopted until 1882. The faculty consists of 17 professors and 44 lecturers, instructors, etc., 61 in all. Lane Hospital, adjoining the college, the City and County Hospital, containing 464 beds, and the college dispensary furnish clinical material. The requirements for admission are a certificate showing that applicant has passed the regular examination for admission to the University of California, or its equivalent, or graduation from an accredited high school or academy, or its equivalent. The college itself does not hold entrance examinations. The college building supplies large laboratory and lecture-room facilities. The curriculum covers a graded course of four years of eight and a half months each. Fees: Matriculation, $5; course fee for each year, $150; laboratory fee for each year, $10; breakage deposit each year, $10; graduation fee, $25; no other charges. The Dean is Dr. Henry Gibbons, Jr. Total registration for 1904-5 was 155; graduates, 37. The next session opens Aug. 15, 1905, and will close May 10, 1906.

UNIVERSITY OF CALIFORNIA, MEDICAL DEPARTMENT.—This department of the State University was organized in 1872, and has a faculty composed of 20 professors, 39 associates and assistants, a total of 59. The City and County Hospital, which admits students of this school not only to the clinics proper, but also to its wards for study, and the college dispensary furnish good clinical material. The course covers graded work for four years of nine months each. This school is a member of the Association of American Medical Colleges. In 1905 two full college years' work will be required of all applicants for admission. The fees are: Matriculation, $5; tuition, $150 each year; laboratory fees extra. The Dean is Dr. Arnold A. D'Ancona. Total registration for 1904-5 was 104; graduates, 17. The thirty-third session opens Aug. 15, 1905, and will close May 15, 1906.

COLLEGE OF PHYSICIANS AND SURGEONS OF SAN FRANCISCO.—This school was organized in 1896 and has a faculty of 22 professors and 24 associate professors and teachers, a total of 46. The hospital facilities consist of the City and County Hospital, the California General Hospital, with 50 beds, and St. Winifred Hospital, with 50 beds. The daily clinics at the new college building furnish abundant material of every description. Applicants for matriculation must show an equal amount of work done or pass a satisfactory examination in English, history and go [illegible] physics, mathematics and Latin, grammar a [illegible] college building recently completed is well [illegible] atories and lecture rooms. This college now conducts a continuous course of medical instruction. Each year is divided into four quarters of three months each, and known as the autumn, winter, spring and summer quarters. Students may enter at the beginning of any quarter. Attendance on 12 quarters will be required, and at least 45 months must elapse between the beginning of the first course and the time of graduation. Fees, $30 per quarter. The Dean is Dr. D. A. Hodghead. Registration for 1904-5 was 144; graduates, 29. The autumn quarter opens Sept. 1, 1905, and closes May, 1906.

HAHNEMANN MEDICAL COLLEGE OF THE PACIFIC.—Homeopathic. This school was organized in 1884, and has a faculty of 19 professors and 23 lecturers, instructors, etc., in all 42. The Pacific Homeopathic Polyclinic, the Homeopathic Sanatorium, the San Francisco Nursery for Homeless Children, Marie Kip Orphanage, accommodating, respectively, 45, 75 and 120 beds; Fabiola Hospital and the City and County Hospital, furnish the clinical material for study. Matriculants must possess the equivalent of a high school education. One year after entrance is permitted in which the student may complete conditions in Latin. The college is registered and accredited with New York State Regents and the Illinois and Michigan State Boards of Health. The course includes four years of seven months each. Total fees for the first year, $155, and $100 for each of the other three years. The Dean is Dr. James W. Ward, 606 Sutter St., San Francisco. Total registration for 1904-5 was 34; graduates, 10. The twenty-third session begins Sept. 1, 1905, and will close May 1, 1906.

CALIFORNIA MEDICAL COLLEGE.—Eclectic. This school was organized in 1884 and has a faculty of 19 professors and 25 lecturers, and instructors, a total of 26. The clinical material is supplied by the Buena Vista and City and County hospitals. Applicants for admission not holding diploma or certificate are examined. The course has been extended to cover four years of eight months each. Total fees are about $110 for each of the first three years and $40 for the fourth year. The Dean is Dr. D. Maclean. Total registration for 1904-5 was 40; graduates, 8. The next session begins Oct. 2, 1905, and ends May 16, 1906.

Los Angeles.

UNIVERSITY OF SOUTHERN CALIFORNIA COLLEGE OF MEDICINE.—This school was organized in 1885, and has a faculty of 29 professors and 19 instructors, 48 in all. The County Hospital, having 200 beds, the Sisters' Hospital of 150 beds, the Children's Hospital of 20 beds, and a college dispensary furnish clinical material. Applicants for admission must give evidence of matriculation in a university or graduation from an accredited high school, academy, preparatory school or a California State Normal School, or a certificate from an appointed member of a high school faculty that applicant has filled the requirements of the Association of American Medical Colleges, of which this college is a member. This college gives no admission examinations. The building is provided with laboratories, amphitheater and lecture rooms, and a new clinical laboratory, erected in 1904, costing, with equipment, $20,000. A graded course, covering four years of thirty-two weeks each, is offered. The total fees for the first year are $145; second and third, $150 each, and $40 for the fourth year. The Dean is Dr. Walter Lindley. Total registration for 1904-5 was 115; graduates, 24. The next session opens Oct. 5, 1905, and closes June 16, 1906.

College of Physicians and Surgeons.—This school was organized in 1903. The length of each course is eight months. The faculty numbers 30 in all, 21 professors and 9 assistants. The registration for 1904-5 was 25; graduates, 13. The next session begins Oct. 4, 1905, and ends June 4, 1906. The Secretary is Dr. Benjamin F. Church, Frost Bldg., Los Angeles.

COLORADO.

Colorado, with a population of 539,700, has three medical colleges. Two of these, Denver and Gross College of Medicine and Denver Homeopathic College are in Denver, which has a population of about 175,000, the other, the Colorado School of Medicine, is at Boulder (population 6,150). The clinical facilities in Denver available to the two colleges are the Denver County Hospital, which has a capacity of 300 beds. St. Joseph's Hospital, with 300 beds, and St. Luke's Hospital, with 75 beds. The Public Library contains 10,000 volumes on medicine. Board can be obtained in Denver for $5 a week and upward.

Denver.

The Denver and Gross College of Medicine.—This is the Medical Department of the University of Denver, and was organized in 1902 by the union of the Gross Medical College (organized 1887) and the Denver College of Medicine (organized 1880). The clinical advantages are the college dispensary, the Denver County Hospital, St. Luke's Hospital, St. Anthony's Hospital, St. Joseph's Hospital, National Jewish Hospital for Consumptives, Home for Dependent Children and the City Contagious Hospital and Mercy Sanitarium. The faculty is made up of 38 professors, 43 assistants and instructors, a total of 81. Its location is central, and the buildings are well arranged for laboratory, dispensary and didactic work. The course is graded and covers four years of eight months. The college is a member of the Association of American Medical Colleges. Final examinations at the end of each year are held. Fees for the first year are $115. For the second year, $116. Third year, $101. Fourth year, $126. Total registration, 1904-5 was 115; graduates, 32. The twenty-fourth session will begin Sept. 10, 1905, and close May 18, 1906. The Dean is Dr. S. G. Bonney.

Denver Homeopathic College.—This college, organized in 1894, beside clinical privileges in the hospital of the city and county of Denver, has exclusive privileges for clinical work in the Denver Homeopathic Hospital, the Haven and the Belle Lenox Nursery. The faculty numbers 26 professors and 7 lecturers and instructors, 33 in all. The requirements for admission are, "possession of a diploma from a literary college, university, an academy, a normal or high school; a first-grade teacher's certificate, or a previous matriculation at some reputable literary or medical college." The course of study consists of four years of seven months each; monthly examinations are held in each subject. A five-year scholarship may be had for $300 payable in advance, otherwise the tuition is $100 a year for the first, second and third years. Senior year, $75. There is a matriculation fee of $5, payable once. The Dean is Dr. James P. Willard. Total registration for 1904-5 was 29; the number of graduates, 6. The eleventh session begins in September, 1905, and will close April, 1906.

Boulder.

Colorado School of Medicine.—This is the Medical Department of the University of Colorado, and was opened in 1883. The University Hospital, under the control of the state, is equipped to accommodate 40 patients, and furnishes free clinical material. Both hospital and dispensary clinics are offered and the sanatorium located at Boulder offers additional advantages in this line. The faculty embraces 18 professors and 9 lecturers and assistants, a total of 27. The laboratories are well equipped and commodious. A separate building is devoted to the study of anatomy and another one is used for medical work exclusively. A complete four-year course of study in a recognized high school, or its equivalent, is required for admission. This school is a member of the Association of American Medical Colleges. The work embraces a graded course of four years of nine months each. The tuition is $50 per year; there are no other fees. The Dean is Dr. Luman M. Giffin. Total registration for 1904-5 was 54; graduates, 6. The twenty-fourth session begins Sept. 11, 1905, and closes June 7, 1906.

CONNECTICUT.

Connecticut, with a population of 908,420, has only one medical college, located in New Haven, population, 115,000. Board and lodging cost $4.50 and upward per week.

New Haven.

Yale Medical School.—This is the Department of Medicine of Yale University. In 1810 a charter was granted for the establishment of this school, and in 1813 it was organized as the Medical Institution of Yale College. In 1879 a new charter changed the name to the one now used, and in 1884 the Connecticut Medical Society, which, from the granting of the first charter, had taken an active part in its control, surrendered its authority, and the University authorities assumed full control. The clinical advantages are embraced under the New Haven Hospital, which contains 175 beds and is the general hospital for New Haven; the Springside Hospital, which is connected with the city almshouse, and the State Hospital for the Insane, located in Middletown, about twenty-five miles distant, which, with its 1,800 patients, offers an opportunity for special instruction in insanity in addition to the clinics. Beside these, the University has just completed a $100,000 building for the dispensary service, which offers good material for clinical teaching. The faculty embraces 14 professors, 5 lecturers, 10 instructors and 19 assistants, a total of 48. The lecture rooms and laboratories are large and well equipped. Matriculants are admitted without examination, provided that they have received a degree in arts or sciences, that they present certificates showing that they have successfully prosecuted the subjects of the examination at some college, high school, academy or preparatory school approved by the faculty, or that they have passed matriculation examinations equivalent to those required at some approved professional school. This school is a member of the Association of American Medical Colleges. The course covers a four-year graded curriculum, nine months constituting a school year; the first two years the fundamental branches are studied, the third year is devoted to a systematic teaching of medicine, surgery, obstetrics and pharmacology, and in the fourth year clinical work, with medicine, surgery and the specialties, is presented. The fees are $150 each year; in the first year there are additional fees amounting to $18, and in the second, $8, and there is a graduation fee of $10. The Dean is Dr. Herbert E. Smith, New Haven. During the session of 1904-5 there were 139 matriculants and 22 graduates. The ninety-third session opens Sept. 28, 1905, and closes June 27, 1906.

DISTRICT OF COLUMBIA.

Washington, population 278,718, has three medical colleges: George Washington University Department of Medicine, *Georgetown University School of Medicine, and Howard* University Medical Department. Washington offers to the student of medicine many advantages. The Army Medical Museum, the Museum of Hygiene, the National Museum, the library in the Surgeon-General's office, the Toner Medical Library and Museum of Hygiene, in all over 125,000 volumes on medicine, open to the medical student a most profitable field. The clinical advantages offered by the various hospitals are good. Owing to the many boarding houses and hotels, board and lodging can be had at reasonable rates.

Washington.

The George Washington University, Department of Medicine.—This school was organized in 1821 as the Department of Medicine of Columbian College, which in 1873 became Columbian University, and in 1904, by an act of Congress, changed its name to the George Washington University. In connection with the Department of Medicine is the University Hospital, established and maintained to afford clinical facilities for the students of the school. Beside the University Hospital, the Garfield Hospital, the Children's Hospital, the Central Dispensary and Emergency Hospital, the Providence Hospital, the Columbia Hospital, the Episcopal Eye and Ear Hospital, the U. S. Government Hospital for the Insane, and the Lutheran Eye and Ear Infirmary afford additional opportunities and are utilized for clinical instruction under the supervision of those members of the faculty who are on the visiting staffs of these institutions. Attendance on clinics is obligatory on third and fourth-year students. The faculty is composed of 34 professors and 30 demonstrators, instructors and assistants. This school is a member of the Association of American Medical Colleges. The laboratories are modern and equipped with all the needed apparatus *for thorough work and instruction. Facilities are also* provided for post-graduate and research work. The course of instruction is graded and extends through four years, each scholastic year consisting of eight months. Written and practical examinations are held during the term and written and oral in all subjects at the end of the school year. The total fees for the first year are $142; for the second year, $117; for the third year, $112, and for the fourth year, $122. A breakage deposit of $10 is required. The Dean is Dr. W. F. R. Phillips, 1607 16th St. N. W. New and commodious buildings were erected and occupied in 1902. The total registration of students for the session of 1904-5 was 298; graduates, 69. The eighty-fourth session begins Sept. 27, 1905, and closes June 6, 1906.

Georgetown University School of Medicine.—This school organized in 1850, controls the Georgetown University Hospital, which affords excellent facilities for clinical teaching and ward classes. Clinics are also held for the benefit of the students in Providence Hospital, containing 500 beds, at the Government Hospital for the Insane, containing over 2,000 beds; in the Children's Hospital, the Central Dispensary, Emergency Hospital and the Garfield Hospital. Attendance on clinical instruction is obligatory in the third and fourth years. The faculty contains 26 professors, 27 instructors and assistants, total 53. This school is a member of the Association of American Medical Colleges. The building is conveniently located and contains spacious and well-ventilated lecture rooms, laboratories and library; the laboratories are equipped with the most approved instruments and appliances. The complete course of study extends over four terms of eight months each. Examinations are held at the end of each session. The fees are $110 each year. The Dean is Dr. George M. Kober, 1600 T St. The registration for 1904-5 was 127; graduates, 16. The next term opens on Sept. 28, 1905, and ends May 31, 1906.

Howard University Medical Department.—This institution was organized in 1867, and "in conformity with the spirit of the organic law of the University, is open to all, without regard to sex or race, who are qualified by good moral character, proper age and suitable education." The removal of any racial distinction has been taken advantage of by colored students, who compose a majority of tho[illegible] a number of white students are also receivir[illegible] reedman's Hospital is a general hospital of [illegible] comprises 17 professors and 16 lecturers and assistants, 33 in all. This college is a member of the Association of American Medical Colleges. Students are required to attend four courses of lectures in separate years of nine months each. The fees of each session are $80, plus $2 per part for dissecting material, and $10 for graduation. Board can be had at the school dining hall for $9 a month, and a room in the dormitory for $15 a term. The Dean is Dr. Robert Reyburn, 2129 F St. Registration for 1904-5 was 153; graduates, 32. The thirty-eighth session begins Oct. 2, 1905, and closes June 1, 1906.

GEORGIA.

Georgia, population 2,216,331, has three medical colleges: Medical College of Georgia, located in Augusta (population 39,441); Atlanta College of Physicians and Surgeons, and Georgia College of Eclectic Medicine and Surgery, both in Atlanta (a manufacturing city of 89,872 population). Board and lodging may be obtained for from $3 to $5 per week.

Augusta.

University of Georgia Medical Department.—This school was organized as a medical academy in 1829, and in 1873 was made the Medical Department of the University of Georgia. Its faculty includes 12 professors and 13 assistants, 25 in all. The course is four years of six months each. Applicants for admission must, by examination, certificate or diploma, show that they possess educational qualifications equal to those required for second grade teachers in public schools; if they are deficient on examination, however, they are admitted, and they may remove the conditions any time before they appear for graduation. The City Hospital, with 130 beds; Lamar Hospital, with 80 beds; the Polyclinic and the Hospital for Contagious Diseases supply clinical material. Fees for the first two years are $75 each; third year, $100, and $130 for the last year. The Dean is Dr. DeSaussure Ford. Total enrolment for 1904-5 was 108; graduates, 14. The seventy-fourth session begins Oct. 1, 1905, and closes April 1, 1906.

Atlanta.

Atlanta College of Physicians and Surgeons.—This school was formed in 1898 by the consolidation of the Atlanta Medical College, organized in 1854, with the Southern Medical College, organized in 1879. It has a faculty of 13 professors and 30 assistants, a total of 43. Clinical facilities are furnished by the Grady Hospital, which is the general hospital for Atlanta, clinics are free to the graduating class. First course students are required to "give satisfactory evidence to the faculty of such educational qualifications as will be deemed necessary for the successful prosecution of their medical studies. These requirements will be similar to those of other reputable medical colleges in the country." The *course of study covers four years of six months each* and is graded. The buildings are large and a new building for practical anatomy has been added. Fees: First and second years, $75 each; *third and fourth, $100 each.* The Dean is Dr. W. S. Kendrick, 71 Washington St. Total registration of students for 1904-5 was 250; graduates, 48. Next session begins Oct. 4, 1905, and closes April 5, 1906.

Georgia College of Eclectic Medicine and Surgery.—This school was organized in 1839, and has a faculty of 16. The college dispensary, Grady Hospital and Georgia Eclectic Hospital furnish clinical material. Applicants for admission must adhere to the requirements established in the National Confederation of Eclectic Colleges, of which this college is a member. The curriculum covers four years of six months each. The Proctor is Dr. W. M. Durham, 77½ Peachtree St. Total number of students for 1904-5 was 53; graduates, 14. The next session opens Oct. 4, 1905, and closes April 4, 1906.

ILLINOIS.

Illinois, population, 4,821,550, has 13 medical colleges, all located in Chicago, a city of about 2,000,000 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, Hahnemann Medical College, Bennett College of Eclectic Medicine and Surgery, College of Physicians and Surgeons, Hering Medical College, Jenner Medical College, Illinois Medical College, American Medical Missionary College, College of Medicine and Surgery, National Medical University, American College of Medicine and Surgery, and Dearborn Medical College. Room and board cost $3 a week and upward.

Colleges in Illinois have to admit students in conformity with the minimum requirements of the Illinois State Board of Health, as follows: "A diploma or certificate of graduation from a high school; or a certificate signed by a principal of a regularly organized high school or by the examiner of the faculty of a recognized literary or scientific college or university, or by the state superintendent of public instruction, or a superintendent of public schools, of having successfully passed an examination in all the several branches embraced in the curriculum of a four years' high school course. The matriculation examination shall not be conducted by any member of the faculty of the medical college. The Illinois State Board of Health will require each applicant for a state certificate to present documentary evidence of his preliminary education, together with his medical diploma, when taking the examination of the board." These conditions will govern all persons admitted to the freshman year on or after Jan. 1, 1903.

Chicago.

Rush Medical College.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 to 1898, and in the latter year became affiliated with the University of Chicago. The faculty is composed of 64 professors, 170 associates, instructors, etc., a total of 234. Good clinical facilities are furnished by Cook County Hospital, caring for about 20,000 patients yearly; Presbyterian Hospital, with 250 beds; a college dispensary, and an obstetric department. In addition to these, extramural clinical courses are offered at the West Side Hebrew Dispensary, St. Luke's Hospital, St. Anthony's Hospital, the Alexian Brothers' Hospital, Illinois Charitable Eye and Ear Infirmary and Chicago Isolation Hospital. Bedside instruction is given. The requirements for admission are those of admission to the better universities or colleges, and, in addition thereto, two years of college work. This college work must have included thorough courses in college chemistry (both inorganic and organic), college physics and biology, all with laboratory work, a reading knowledge of German and French. By the addition of a recently completed seven-story building, the facilities for clinical instruction are largely increased. The laboratories and their equipment are unexcelled. The curriculum covers graded work for four years of three quarters each, a quarter being three months. A fifth year, consisting of a hospital interneship or of a fellowship in one of the departments is offered, but, for the present, is optional. A continuous session is held, but credit for more than three quarters can not be obtained in any calendar year. A combined course for six years confers degrees of both science and medicine. All freshmen and sophomore studies are given at the University of Chicago. The total fees are $180 this year. Students in continuous attendance, i. e., three quarters in twelve months, may complete their course by paying the fees in vogue when they first entered the college. A matriculation fee of $5 is paid but once, and there are incidentals amounting to from $2 to $5 annually. The Deans are Dr. Frank Billings, 100 State St., and Dr. John M. Dodson, 34 Washington St. Total registration, 1904-5, was 522; graduates, 112. The fiscal year begins July 1; final examinations are held at the end each quarter.

College of Physicians and Surgeons.—This school was organized in 1881, and in 1896 became the Medical Department of the University of Illinois. The faculty is composed of 39 professors, 105 assistants and instructors, a total of 144. The West Side Hospital, containing 125 beds; Cook County Hospital, and a college dispensary and maternity clinic supply most of the clinical material, but under certain conditions students of this school are admitted to the following hospitals for clinical study: Augustana, Baptist, Chicago, Woman's, Samaritan, Alexian Brothers', St. Mary's, and the Chicago Lying-in. This school is a member of the Association of American Medical Colleges. A magnificent building has recently been added to the college, and the laboratory, amphitheater and lecture-room space and equipment are excellent. The collegiate year is divided into two terms; the winter term of thirty-six weeks and the summer term of twelve weeks, of actual teaching. Attendance on the winter term is required in order to secure credit for a year's work, and attendance on four winter terms is required for graduation. Attendance on the summer term is optional, and the work is supplementary to the work of the winter term. Students may obtain credit for work done in certain branches, but attendance on this term does not apply on the required thirty-six months' attendance necessary for graduation. The fees are $145 each for the first two years, $130 for the third and $160 for the fourth year. The Dean is Dr. William E. Quine, 103 State St. Total registration for 1904-5 was 654; graduates, 213. The fall term begins Sept. 26, 1905, and ends June 5, 1906.

Northwestern University Medical School.—This school was organized in 1859 as the Medical [illegible] iversity, became independent as the Chicago [illegible] , and in 1869 assumed its present relation [illegible] of Northwestern University. The faculty [illegible] and 75 assist[illegible] with 225 beds; [illegible] 400 beds; Provident Hospital, 100 b[illegible] nd a college free dispensary furnish [illegible] udy to students of this college exclus[illegible] ople's, and the Chicago Lying-in hospitals are also open to them for study. Applicants for admission must, by diploma, certificate or examination, show possession of the educational requirements required to enter the College of Liberal Arts of Northwestern University. This school is a member of the Association of American Medical Colleges. The laboratory and lecture-room facilities are ample and the equipment is good. The course of study covers graded work for four years of thirty-six weeks each. Optional summer laboratory and clinical courses are also given. Final examinations are held at the end of each semester. The fees for each year are $175, and a matriculation fee of $5, paid once, is charged. The Dean is Dr. N. S. Davis, Chicago Savings Bank Bldg. The total registration for 1904-5 was 593; graduates, 143. The next session opens Oct. 3, 1905, and closes June 1, 1906.

American Medical Missionary College.—This school was organized in 1895 and has the primal object of educating men and women as missionary physicians. The faculty numbers 26. The didactics and laboratory work, covering the first two years, are carried on at Battle Creek, Mich., and the clinical studies in Chicago. A hospital with 20 beds, in connection with the college, together with a free college dispensary with an obstetric department, supply material for practical work. The college is a member of the Association of American Medical Colleges. The course covers four years of nine months each. Total fees are $125 for each of the four years. The Secretary is Dr. E. L. Eggleston, Battle Creek, Mich. Total registration for 1904-5 was 80; graduates, 21. The eleventh session opens Sept. 20, 1905, and closes June 19, 1906.

Illinois Medical College.—This school, organized in 1894, has a faculty of 31 professors and 20 assistants, a total of 51. A college dispensary and Cook County Hospital are available for clinical study. The requirements of admission include a high school diploma or its equivalent. The college is a member of the Association of American Medical Colleges. Attendance for seven months during each year is necessary for graduation. Total fees are about $125 for each year. The Dean is Dr. B. B. Eads, 103 State St. Total registration for 1904-5 was 192; graduates, 59. The next fall term begins Sept. 4, 1905.

Dearborn Medical College.—This school was organized in 1903, with a faculty of 38 professors and 4 assistants, a total of 42. The instruction, which is given in the evening only, extends over a period of four years of ten months each. Cook County Hospital, Samaritan Hospital and a college dispensary supply the clinical material. The total fees are: $5 matriculation fee, $110 tuition, and $10 laboratory deposit. The Dean is Dr. L. Blake Baldwin; the Secretary, Dr. J. L. Wells. Total registration for 1904-5 was

181; graduates, 29. The next session begins Sept. 4, 1905, and ends June 23, 1906.

Hahnemann Medical College.—Homeopathic. This school was organized in 1855, and has a faculty of 104. Hahnemann Hospital and a college dispensary supply clinical material. The requirements for admission are a high school diploma or its equivalent. The course is four years of seven months each. Fees: Matriculation, paid once, $5; each semester, $50, and hospital tickets, $5 each for third and fourth years. The Registrar is Dr. W. Henry Wilson. Total registration 1904-5, 220: graduates, 61. The next session begins Sept. 27, 1905.

Hering Medical College.—Homeopathic. This school was organized in 1892. Dunham Medical College, organized in 1895, was consolidated with this school in August, 1902. In January, 1905, it purchased the Chicago Homeopathic College Building at 354 South Wood St., opposite Cook County Hospital, which it now occupies. The faculty comprises 40 professors and 25 associates, lecturers, etc., in all 65. Hering College Hospital, Chicago Homeopathic, Frances Willard and Cook County hospitals supply clinical facilities. The course covers four years of eight months each. The total fees for a full course are $300 if paid in advance, or $100 per year. The Dean is Dr. H. C. Allen. Total registration for 1904-5 was 50; graduates, 14. The fourteenth session begins Sept. 4, 1905, and ends May 3, 1906.

College of Medicine and Surgery.—Physio-Medical. This school was organized in 1896, and has a faculty of 48 professors and 14 assistants. Three college dispensaries supply material for clinical work. The course covers four years of nine months each, divided into 3 semesters of three months each. Fees for the first, second and third years, $100 each, and $115 for the fourth. The Secretary is Dr. Franklyn J. Morgan, 67 Wabash Ave. Total registration for 1904-5 was 89; graduates, 14. The next session begins Sept. 25, 1905, and ends June 28, 1906.

Bennett College of Eclectic Medicine and Surgery.—This school, organized in 1868, has a faculty of 40 professors and 12 assistants, 52 in all. The Bennett, Cook County and Baptist hospitals and a college dispensary supply clinical facilities. Matriculants must present a diploma or certificate or pass a satisfactory examination "in conformity with the minimum requirements of the State Board of Health." This course covers four years of twenty-six weeks each. This school is a member of the National Confederation of Eclectic Medical Colleges. Fees for each year are $100, with a matriculation fee, paid once, of $5. The Dean is Dr. A. L. Clark, Elgin, Ill. Total registration, 1904-5 was 103; graduates, 30. The thirty-eighth session begins Sept. 26, 1905, and ends May 8, 1906.

American College of Medicine and Surgery.—This school was founded in 1901 and has a faculty of 65. The requirements for entrance are graduation from an accredited high school or equivalent. The course is four years of eight months each. Frances E. Willard and Cook County hospitals supply clinical material. The Secretary is Dr. J. N. Roe. The annual fee is $100; matriculation fee is $5; a total fee for one year, with board, room, light and heat, is $208. The enrolment, 1904-5, was 292; graduates, 34. The next session begins Sept. 26, 1905, and closes May 15, 1906.

National Medical University.—This school was organized in 1891, and its courses include instruction in the methods of all the so-called schools of practice, including manual therapeutics. The faculty numbers 66. The requirements for entrance are in accordance with the requirements of the Illinois State Board of Health. Each year is divided into four quarters of thirteen weeks each, attendance on three quarters constituting one college year. The fees are $200 per year. The Dean is Dr. L. D. Rogers, 533 Wells St. Total matriculants for 1904-5 were 232; graduates, 29. The autumn quarter will begin Oct. 1, 1905.

Jenner Medical College.—This is a day and evening school, organized in 1892. The faculty consists of 46 professors and 7 assistants, 53 in all. Cook County Hospital and college dispensary supply clinical material. The course covers four years of 40 weeks each and embraces laboratory, didactic and clinical instruction. The total fees each year are $100, with a $5 matriculation fee, paid but once. The Registrar is Dr. C. Shorman, 163 Randolph St. Total enrolment for 1904-5 was 102; graduates, 13. The next session begins Sept. 4, 1905, and will end June 29, 1906.

Harvey Medical College.—This is a night school, which was organized in 1891 and became extinct in 1905. Total registration for 1904-5 was 210; graduates, 18.

INDIANA.

Indiana, population 2,516,462, has six medical colleges. Four are situated in Indianapolis, a city of 169,164 people: The Central College of Physicians and Surgeons, Medical College of Indiana, the Eclectic Medical College and the Physio-Medical College of Indiana. The clinical facilities of Indianapolis are good, and board and lodging can be obtained from $3 a week and upward. The Fort Wayne College of Medicine is situated in Fort Wayne, a railroad and manufacturing town of 45,115 inhabitants. Board and room can be obtained there at an average of $3 a week. The School of Medicine, Indiana University is situated in Bloomington, a city of 5,000.

Indianapolis.

Central College of Physicians and Surgeons.—This school was organized in 1879 and reorganized in 1901. The faculty numbers 24 professors and 35 lecturers and demonstrators, total 59. A new college building has been erected in the center of the city on the most up-to-date plans. Its floor space comprises 25,000 square feet, more than half of which is devoted to laboratory teaching. The school gives instruction largely by laboratory and clinical methods. Clinical facilities are furnished by a dispensary maintained by the college, by the City Dispensary, City Hospital, St. Vincent's Infirmary and the Central Hospital for the Insane. Bedside clinics are given to sections of senior class daily at City Hospital. This college was a charter member of the Association of American Medical Colleges. The course is four years of seven months each. The Dean is Dr. George D. Kahlo; the Secretary, Dr. John F. Barnhill. The fees are $75 for each year. Total registration, 1904-5, was 146; graduates, 25. The session for 1905-6 will open Sept. 20, 1905, and closes April 20, 1906.

Medical College of Indiana.—This is the Medical Department of the University of Indianapolis, and was organized in 1869. The faculty embraces 25 professors, 38 adjuncts, lecturers, etc., a total of 63. The City Hospital, containing 200 beds; Indianapolis Dispensary; Central Hospital for the Insane, with a capacity for 1,800 patients; St. Vincent's and the Maternity hospitals, and a college dispensary provide clinical facilities; the wards in the charity hospitals are open to students of this college for bedside instruction. The laboratory and lecture-room space is ample. This college is a member of the Association of American Medical Colleges. The course extends over four years of seven months each. Fees, $75 for first, second and third years, and $100 for the fourth year, which includes graduation. The Dean is Dr. Henry Jameson, Newton-Claypool Bldg. Total enrolment for 1904-5 was 269; graduates, 78. The thirty-sixth session opens Sept. 14, 1905, and closes May 1, 1906.

Eclectic Medical College of Indiana.—This school was organized in 1900 and has a teaching force of 24. The course is four years of six months each. Fees: For each year, $75, or for all four, $225; $25 for graduation. Total [illegible] 44; graduates, 8. The Dean is Dr. W. M. [illegible] Ave. The Secretary is F. M. Wright, M.D., 11[illegible] The next session begins Sept. 26, 1905, and ends April 16, 1906.

Physio-Medical College of Indiana.—This school was organized in 1873, and has a faculty of 30. The course is four years of seven months each. Total fees for each year are $70. The Secretary is Dr. C. T. Bedford, Newton-Claypool Bldg. Total enrollment, 1904-5 was 72; graduates, 5. The next session begins Sept. 13, 1905, and closes April 13, 1906.

Fort Wayne.

Fort Wayne College of Medicine.—This school is the Medical Department of the Ohio Northern University, located at Ada, and was organized in 1879. It has a faculty of 27 professors and 9 lecturers and assistants, a total of 36. St. Joseph's Hospital, with a capacity of 250 patients; Hope Hospital, with 200 beds; St. Roche's Hospital, having accommodation for 35 patients; Indiana School for Feeble-Minded Youth and Allen County Orphan Asylum, capable of holding 150 children, supply the clinical facilities. This school is a member of the Association of American Medical Colleges. The curriculum covers four years of seven months each. The course is practical, supplemented by lectures and laboratory work. The total fees for each year are $75, with an additional $5 matriculation fee, payable once. The Dean is Dr. C. B. Stemen, 715 Broadway. Total registration, 1904-5, was 43; graduates, 6. The next session opens Sept. 12, 1905, and closes April 18, 1906.

Bloomington.

Indiana University School of Medicine.—This school was organized in 1903, and gives only the first two years of the medical course, extending over nine months in each year. The school is a member of the Association of American Medical Colleges. The faculty consists of 8 professors and 3 assistants, a total of 11. Dr. Burton D. Myers is the Acting Dean. The enrolment in 1904-5 was 14. The next session begins Sept. 18, 1905, and ends June 22, 1906.

IOWA.

Iowa, population, 2,231,853, has five medical colleges. The College of Medicine of the State University of Iowa and the College of Homeopathic Medicine of the State University of Iowa are located in Iowa City (population 10,000). In Des Moines (population 62,139) is the College of Medicine of Drake University. In Sioux City (population 33,111) is the Sioux City College of Medicine. In Keokuk (population 15,641) is Keokuk Medical College, College of Physicians and Surgeons. Board and lodging may be had in Des Moines for $15 a month and upward and in the other cities named for from $2.50 to $5 per week.

Des Moines.

Drake University College of Medicine.—This school was organized in 1882 under the name of the Iowa College of Physicians and Surgeons. In 1900 it became affiliated with Drake University. The faculty consists of 21 professors and 25 assistants, a total of 46. The Mercy and Methodist hospitals and a large dispensary clinic furnish clinical material. The college is a member of the Association of American Medical Colleges. The requirements for admission, after the 1st of July, 1905, will be a full four years' high school course or its equivalent. The work covers a graded course of four years of nine months each. The total fees for the first two years are $107 each, including laboratory and dissecting material; for the last two years, $89 each, including hospital fees. The Dean is Dr. D. S. Fairchild. The total registration for 1904-5 was 60; graduates, 12. The next session begins Sept. 18, 1905, and ends June 14, 1906.

Iowa City.

College of Medicine of the State University of Iowa.—This department was organized in 1870. The faculty is made up of 15 professors, 34 lecturers, demonstrators and assistants, a total of 49. The University Hospital, built in 1897, at a cost of $50,000, supplies the clinical material. The school is a member of the Association [illegible] Medical Colleges. The course of study covers f[illegible] weeks each, embracing graded laboratory, [illegible] ork. New laboratories have been erected. histology, embryology, anatomy, physiology, pharmacology, pathology, bacteriology and clinical medicine. Combined courses leading to more than one degree are offered. Total fees for each year are $50. The Dean is Dr. James R. Guthrie, Dubuque; Secretary, Dr.

W. L. Bierring, Iowa City. Total number of students registered for 1904 5 was 277; graduates, 65. The thirty-sixth session opens Sept. 21, 1905, and ends *June 13, 1906.*

College of Homeopathic Medicine of the State University of Iowa.—This was organized in 1877. The faculty is composed of 12 professors and 12 lecturers and assistants, a total of 24, but some of these are of the faculty of the College of Medicine. The requirements for admission, and the work, with the exception of that pertaining to homeopathy, are the same as those for the other department. The fees are *also the same.* The Dean is Dr. George Royal, Des Moines. Total registration for 1904-5 was 41; graduates, 9. The twenty-ninth session begins Sept. 21, 1905, and will end June.13, 1906.

Keokuk.

Keokuk Medical College, College of Physicians and Surgeons.—In 1849 the College of Physicians and Surgeons, Keokuk, was organized, and four years later it became the Medical Department of the University of Iowa, continuing as such until 1870, when the original name was resumed. By the union, in 1899, of this college with the Keokuk Medical College, organized in 1890, the present school under the above name was founded. The clinical material is good. St. Joseph's Hospital is open to the student for study and the clinics held there are large and varied. The faculty is composed of 17 professors *and* 3 assistants and demonstrators, 20 in all. This college is a member of the Association of American Medical Colleges. The studies embrace a graded course of four years of seven months each. The total fees for the first year are $63; for the second and third, $58 each, and $53 for the last year. *The Secretary* is Dr. *C. E. Ruth. Total registration for* 1904-5 was 230; graduates, 50. The next session begins Sept. 19, *1905, and ends April 24, 1906.*

Sioux City.

Sioux City College of Medicine.—This school was organized in 1891. The faculty numbers 26. Clinical material is supplied by St. Joseph's, Mercy and Samaritan Hospitals and a college dispensary. This college is a member of the Association of American Medical Colleges. The system *of study* embraces a four-year graded course, eight months being a school year. Final examinations are held at *the close of each course* of instruction. Matriculation fee, paid but once, $5; tuition, each year, $48; hospital fee, $5, and graduating fee, $20. The *President* is Dr. J. N. Warren. *Total* number of students registered, 1904-5, was 72; graduates, 14. The sixteenth session opens Sept. 13, 1905, and will close May 2, 1906.

KANSAS.

Kansas, population, 1,600,000, has two medical colleges: Kansas Medical College is in Topeka (population 33,608), and the College of Physicians and Surgeons, now a part of the University of Kansas, in Kansas City (population 55,000). In addition there is a school which does not grant degrees, but prepares students in the first two years. This is the Medical School of the University of Kansas, at Lawrence, a town of 10,862 people. Board and lodging in all these places *may be had for $3 to $5 per week.*

Lawrence.

University of Kansas School of Medicine.—This school was organized in 1880. The faculty numbers 18. This school is a member of [illegible] nerican Medical Colleges. Only the purely [illegible] taught in Lawrence, but the work in these is [illegible] weeks being devoted to the two-year course. The greater part of the work is done in the laboratory, with recitations and assigned readings, the lectures being supplementary only. For this reason the equipment and arrangement of the laboratories have been given special attention. A combined course of four years is offered, conferring "the degree of bachelor of arts in medicine." In the year 1905-6 the work will be entirely reorganized. The *third and fourth years'* work will be *added,* but will not be given at Lawrence. A hospital will be erected at Rosedale, Kan., a suburb of Kansas City, and the clinical work will be carried on at this place. The total fees to residents of the state are: First year, $25; second, $25; to non-residents of the state, $35 and statement as to change in fees for next year. The Acting Dean is Dr. Geo. E. Hoxie. The number of students registered for 1904-5 was 32. The next session begins Sept. 6, 1905, and will end June 6, 1906.

Kansas City.

College of Physicians and Surgeons.—This was organized in 1894 as the Medical Department of Kansas City University, and in 1905 was absorbed by the Medical Department of the University of Kansas. The total registration in 1904-5 was 55; graduates, 3.

Topeka.

Kansas Medical College, Medical Department of Washburn College.—This college, organized in 1890, has a faculty of 25 professors and 8 lecturers and assistants, 33 in all. Good material for both medical and surgical clinics is found in Christ's Hospital, with 100 beds, and Topeka State Hospital; the dispensary in the college building also supplies material for class demonstration. The college is a member of the Association of American Medical Colleges. The college building affords ample laboratory and lecture-room space. The course of study is a graded one, covering four years of 30 weeks each. Individual instruction is especially aimed at. The total fees for the first three years are $70 each, and $30 for the last year. The Dean is Dr. William S. Lindsay; Secretary, Dr. William McVey. The *total* registration for 1904-5 was 91; graduates, 18. The sixteenth session begins Sept. 13, 1905, and will close April 18, 1906.

KENTUCKY.

Kentucky, population 2,147,174, has seven medical colleges. *They are all situated in Louisville, a city of about 225,000* inhabitants, and are as follows: University of Louisville Medical Department, Kentucky School of Medicine, Louisville Medical College, Hospital College of Medicine, Southwestern Homeopathic Medical College, Kentucky University Medical Department, and the Louisville National Medical College. Board and lodging in Louisville costs from $3 to $4 per week.

Louisville.

Kentucky School of Medicine.—This school was organized in 1850, and has a faculty composed of 20 professors, 27 lecturers, instructors and assistants, a total of 47. It is a lineal descendant of the Medical Department of [illegible] situated at Lexington, Ky. The [illegible] and the college dispensary furnis[illegible] udy. [illegible] direc[illegible] tient [illegible] beds [illegible] asses [illegible] ge is a [illegible] mer- [illegible] The l[illegible] are [illegible] mbraces a four years' course of [illegible] weeks [illegible] first three years are $75 each; for the [illegible] Dean is Dr. W. H. Wathen, 628½ Fourth Ave. Total number of students *registered for* 1904-5 was 193; graduates, 49. The next session begins Dec. 15, 1905, and will end July 12, 1905.

Louisville Medical College.—This school was organized in 1869 and has a faculty of 12 professors and 18 instructors and assistants, 30 in all. The City Hospital, College Infirmary and a dispensary offer good clinical facilities. Applicants for admission must show by dipl[illegible] mination *that they are sufficiently* proficient [illegible] algebra, physics and such Latin as would be [illegible] study. The laboratories and lecture rooms a[illegible] of study covers four years of six months each. The fees are $75 each year, with graduating fee of $25. The Secretary is Dr. Irvin Abell. Total registration for 1904-5 was 263; graduates 40. The next session opens Dec. 11, 1905, and closes July 1, 1906.

Hospital College of Medicine.—This school is the medical department of Central University of Kentucky and was organized in 1873. The faculty is composed of 16 professors and 35 assistants, lecturers, etc., a total of 51. The Gray Street Infirmary, City Hospital and a well-equipped college dispensary present good facilities *for clinical study. This college is a member of the Association of American* Medical Colleges. Laboratory work, which is a prominent feature of the course, is thorough and practical. The laboratories and amphitheaters are ample in equipment and capacity, and the hospital advantages give opportunity for personal bedside instruction. The course covers four years of seven months each. Total fees for each of first three years, $75, and $100 for the fourth year. The Dean is Dr. P. Richard Taylor. Total enrolment for 1904-5 was 423; graduates, 90. The thirty-second session opens Dec. 1, 1905, and closes July 1, 1906.

Kentucky University Medical Department.—This school was reorganized in 1898. The faculty is composed of 17 professors and 25 lecturers, demonstrators, etc., 42 in all. Broadway Infirmary, the City Hospital and the college dispensary furnish clinical material. The school is a member of the Association of American Medical Colleges. The buildings provide ample facilities for clinical, laboratory and didactic instruction. The course of study embraces graded work for four years of thirty weeks each. Tuition is $75 per session and $25 graduation fees. The Dean is Dr. Thomas C. Evans, 419 West Chestnut St. Total number of students registered in 1904-5 was 340; graduates, 76. The next session begins Jan. 1, 1906, and continues seven months.

University of Louisville Medical Department.—This school was organized in 1837, under the name, Louisville Medical Institute, and in 1846 assumed its present title. It has a faculty of 11 professors and 27 lecturers, demonstrators, etc., a total of 38. The University Hospital, City Hospital, Sts. Mary and Elizabeth Hospital, together with the college dispensary, furnish good clinical material. The course covers graded work *for four years of* seven months each. Total fees: First year, $107; second, $122; third, *$100, and fourth; $112. The Dean is Dr. J. M. Bodine.* Total registration for 1904-5 was 248; graduates, 75. The sixty-eighth session begins Oct. 2, 1905, and ends May 1, 1906.

Louisville National Medical College.—Colored. This was chartered in 1888 and shows a teaching force of 25. There is a four-year course, seven months to the year; the fees are $58, $58, $55 and $50 for the four years respectively. The Dean is Dr. E. S. Porter, *Tenth and Walnut. The attendance* 1904-5 was 37; graduates, 6. The next session opens Oct. 7, 1905, and ends May 17, 1906.

Southwestern Homeopathic Medical College.—This college was organized in 1892, and has a faculty of 17 professors and 10 *lecturers and assistants,* 27 in all. A college dispensary supplies clinical material. The curriculum covers four years of seven months each. Total fees*: First and second years, $80*; third, $70, and $65 for the fourth. The Dean is Dr. A. L. *Monroe.* Total number of students for 1904-5 was 19; graduates, 6. Next session opens Sept. 26, 1905, and closes April 24, 1906.

LOUISIANA.

Louisiana, having a *population* of 1,381,625, contains two medical colleges: Medical Department of the Tulane University of Louisiana and New Orleans University. They are both situated in New Orleans, a city of 287,104 people. The cost of room and board is from $16 to $22 a month.

New Orleans.

Flint Medical College of New Orleans University.—Colored. This school was organized in 1889. The faculty is made up of 7 professors, 4 lecturers and instructors, 11 in all. Clinical material is supplied by the Sarah Goodridge Hospital and by an outdoor clinic. This college is a member of the Association *of American Medical Colleges.* The curriculum covers a graded course of four years, thirty weeks each. The laboratories and lecture rooms are ample. Examinations are held monthly. Total fees for the first, second and third year are $40 each, and $50 for the last year. The President is Dr. F. H. Knight, New Orleans. Total enrolment for 1904-5 was 55; graduates, 7. The sixteenth college year begins Sept. 26, 1905, and will end March 17, 1906.

Medical Department of the Tulane University of Louisiana.—This school was organized in 1834 as the Medical College of Louisiana, and became, by law, in 1847, the Medical Department of the University of Louisiana, and in 1884 the Medical Department of the Tulane University of Louisiana. The faculty and all other instructors number 49. By acts of legislature the Charity Hospital, with its 900 beds, has been opened to the students of this school, *for clinical study, not only in medicine and surgery, but also in* obstetrics and gynecology. In the year 1903 there were 8,813 cases treated in the wards of this hospital; these were indoor patients, and, in addition, 19,302 outdoor patients were treated in the free dispensary department. The Milliken M[illegible] a capacity for 200 children, is also availab[illegible] cases. Bedside instruction is given by the [illegible] these hospitals, and postmortem examinations are held before the students. The laboratories are large and well equipped, and the lecture rooms and recitation rooms are ample. The course of study covers four terms of twenty-eight weeks each. Total fees for the first two years are $135 each, and for the third and fourth, $145 and $170, respectively. The Dean is Dr. Stanford E. Chaille, New Orleans. The total number of medical students registered for 1904-5 was 469; graduates, 83. The seventy-second session begins Oct. 19, 1905, and will close May 2, 1906.

MAINE.

Maine, population 694,466, has one medical college, located in Portland, population 60,000. Board and lodging cost from $3 to $5 a week.

Portland.

Medical School of Maine.—This, the Medical Department of Bowdoin College, was organized in 1820. It has 15 professors and 18 instructors, total 33. Students of the first and second years are instructed in Brunswick, a town of 6,800 inhabitants. The third and fourth year classes are taught in Portland, where are situated the Maine General Hospital and other clinical advantages. Applicants for admission, unless they possess a diploma, are examined in English, arithmetic, algebra, geometry, United States history, physics, chemistry and Latin. The course covers four years of eight months each. The total fees are $120 for the first year for the second and third, $110, and $110 for the fourth year. The Dean is Dr. Alfred Mitchell, Brunswick. Total number of students in 1904-5 was 93; graduates, 18. The next session opens Oct. 19, 1905, and closes June 20, 1906.

MARYLAND.

Maryland, with a population of 1,188,044, contains eight medical colleges, all located in Baltimore, a city with 508,957 inhabitants. They are as follows: School of Medicine of the University of Maryland, College of Physicians and Surgeons, Baltimore University School of Medicine, Baltimore Medical College, Women's Medical College, Southern Homeopathic Medical College, Johns Hopkins Medical School and Maryland Medical College. The Bay View Hospital, having a capacity for 2,000 patients, is open to students for clinical instruction, and furnishes good opportunities for practical demonstrations. Board and lodging can be obtained for from $3 to $5 per week.

Baltimore.

Johns Hopkins Medical School.—This is the Medical Department of Johns Hopkins University, and was organized in 1893. The faculty comprises 11 professors, 71 lecturers, clinical professors, associate professors, associates, instructors and assistants, a total of 82. The Johns Hopkins Hospital and Dispensary furnishes abundant and varied clinical material; the lying-in department of the hospital, opened in 1896, is in successful operation. The requirements for admission demand that the applicant either has, (*a*) completed the chemical-biologic course which leads to the A.B. degree in the university; (*b*) graduated at an approved college or scientific school, and can furnish evidence of an acquaintance with Latin and a fair reading knowledge of French and German, and a knowledge of physics, chemistry and biology, such as may be obtained from a year's course, including laboratory instruction. The school is a member of the Association of American Medical Colleges. The laboratories are large, well lighted and well equipped. The buildings are ample and built expressly for the purpose for which they are used. In the method of instruction special emphasis is laid on practical work in the laboratories, dispensary and wards of the hospital. The first two years are devoted mainly to practical work in the laboratories, combined with demonstrations, recitations and lectures, and during the remainder of the course opportunity for the personal study of cases is given. The work covers a graded course of four years, eight and a half months to the year. Final examinations, partly written and partly oral, include practical tests in laboratory and clinical work; the general character of the student's work is closely watched. The charge for tuition is $200 per annum, with no fees unless a microscope is rented; that fee is $5 a year. The Dean is Dr. William H. Howell, 232 W. Lanvale St. Total registration in 1904-5 was 291; graduates, 55. The next session begins Oct. 3, 1905, and ends June 2, 1906.

University of Maryland School of Medicine.—This institution was organized in 1807 as the College of Medicine of Maryland, and in 1812, other faculties having been added, the whole was chartered under the name of the University of Maryland. The faculty is composed of 14 professors, 46 associates and lecturers, etc., a total of 60. The University Hospital, a part of which is used for a hospital for foreign seamen and another portion for a free city hospital, offers excellent clinical facilities. Beside this, the Presbyterian Eye, Ear and Throat Charity Hospital, in which 11,317 patients were treated in 1902; the Hospital for the Relief of Crippled and Deformed Children, containing 40 beds; the Maternity Hospital, and a college dispensary furnish material for clinical study. This school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are ample and well equipped. An entirely new laboratory building has just been erected. The fourth-year class, divided into sections, receives special training in practical laboratory work in a well-appointed clinical laboratory. Didactic, laboratory and clinical instruction, special attention being paid to bedside work, make up the system of teaching. The course covers four years of eight months each, and is graded. The total fees for the first two years are $135 each; for the third year, $125, and $155 for the final year. The Dean is Dr. R. Dorsey Coale, Baltimore. The total number of students registered in 1904-5 was 340; graduates, 100. The ninety-ninth session begins Oct. 2, 1905, and will terminate June 1, 1906.

Baltimore Medical College.—This college was organized in 1881, and has a faculty of 59. The clinical material is furnished by the Maryland General Hospital, having a capacity of 200 beds; the Maryland Lying-in Hospital; the Mount Hope Retreat, which presents good opportunity for the study of nervous and mental diseases, and a college dispensary, which, beside the great number of ambulatory patients treated, has an outdoor department that permits of the advanced student taking care of charity cases and carrying out his own treatment. This college belongs to the Association of American Medical Colleges. The college buildings afford ample laboratory, clinical and lecture room space. Bedside teaching in the hospital wards is carried on in sections, and every member of the senior class is required to attend throughout the session. The course of study is graded and covers four years of eight months each. The Dean is Dr. David Streett. The total number of students registered in 1904-5 was 406; graduates, 96. The twenty-fifth session opens Sept. 20, 1905, and closes May 20, 1906.

College of Physicians and Surgeons.—This school was organized in 1872, and in 1878 Washington University School of Medicine, established in 1827, was consolidated with it. The faculty numbers 53. The clinical facilities, beside those afforded in common with other schools, are supplied by the Baltimore City Hospital, the Hospital for the Colored Race, containing 100 beds; *the Nursery and Child's Hospital, with 150 beds; the Maryland* Lying-in Asylum and a college dispensary. This school is a member of the Association of American Medical Colleges. The work covers a graded course of four years, eight months constituting a year. Total fees are $115, $115, $115 and $135 for the respective years. The Dean is Dr. Charles F. Brown. The total number of students registered in 1904-5 was 298; graduates, 70. The next session opens Oct. 1, 1905, and closes June 1, 1906.

Maryland Medical College.—This school was organized in 1898 and has a faculty of 19 professors, 25 associates, lecturers, etc., 44 in all. The Franklin Square Hospital, West End Maternite and a college dispensary furnish clinical material. The course of study covers four years of eight months each. A matriculation fee of $5 and total laboratory fees for the four years of $55 are charged; tuition is $75 each year. The Dean is Dr. J. B. Schwatka, 1003 North Broadway. Total registration for 1904-5 was 207; graduates, 93. The eighth session begins Sept. 15, 1905, and closes in May, 1906.

Woman's Medical College.—This school was organized in 1882 and has a faculty of 17 professors, 18 associates, assistants and lecturers, a total of 35. The Hospital of the Woman's Medical College and a college dispensary furnish general clinical material, while abundant special material is furnished by the Presbyterian, Eye and Ear and the Sheppard and Enoch Pratt Hospital (for mental cases). The college is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are equipped with all necessary apparatus; the practical work is emphasized. Eight months constitute a school year and the course covers graded work for four years. The total fees for the first three years are $106 each, and $81 for the last year, with $30 graduation fee. The Dean is Dr. S. Griffith Davis, 1220 Sight St. Total number registered for 1904-5 was 36; graduates, 3. The twenty-fourth session opens Oct. 1, 1905, and closes May 31, 1906.

Southern Homeopathic Medical College.—This school was organized in 1890, and has a faculty of 10 professors, 14 associates and lecturers, a total of 24. The clinical facilities are those offered by [illegible] Hospital, which has 55 beds, and the [illegible] also furnishes clinical material. [illegible] must pass a satisfactory examinat[illegible]phy, history and Latin, unless t[illegible] evidence that they have done a corresponding amount of work. The course covers graded work for four years, seven months to the year. The fees are $105 for the first year, $100 each for the second and third, and $130 for the last year; $350 in advance for the full four years' course, with a reduction in the fees for the fourth year to those whose averages exceed 90 per cent. in previous years. The Dean is Dr. George T. Shower, 421 Roland Ave. Total registration for 1904-5 was 33; graduates, 9. The fifteenth session begins Oct. 3, 1905, and ends May 1, 1906. 1. 1906.

Baltimore University School of Medicine.—This school, organized in 1884, has a faculty of 10 professors and 25 lecturers, demonstrators, etc., in all 35. The Baltimore University Hospital, Lying-in Hospital and the clinical material used in common with the other schools supply the facilities for practical work. The course is four years of six months each. The fees are about $100 each year. The Dean is Dr. Hampson H. Biedler, 119 W. Saratoga St. Total registration for 1904-5 was 79; graduates, 14. The next session opens Oct. 1, 1905, and closes April 1, 1906.

MASSACHUSETTS.

Massachusetts, population 2,805.340, has four medical colleges: Medical School for Harvard University, Boston University School of Medicine, College of Physicians and Surgeons, and Tufts College Medical School. They are all situated in Boston, a city of 603,163 inhabitants. Board and lodging can be obtained from $5 to $7 per week.

Boston.

Medical School of Harvard University.—This was organized in 1782, and has a faculty of 32 professors, 113 associates and assistants, etc., a total of 145. Beside the clinical advantages mentioned, the Boston Lying-in Hospital, the Boston Dispensary, where 43,918 patients were treated last year; the Infants' Hospital, the Children's Hospital, Long Island Hospital, containing 250 beds, and the Marine Hospital, all furnish excellent opportunity to the student for clinical study. Students are also permitted to visit the Free Hospital for Women and Carney Hospital on application to the physicians on duty. Candidates for admission "must present a degree in arts, literature, philosophy or science from a recognized college or scientific school, with the exception of such persons, of suitable age and attainments, as may be admitted by special vote of the faculty in each case. Each candidate is required to hand in the original note book in which he recorded the work performed by him in qualitative analysis, and also to pass a written examination in theoretical and descriptive chemistry. If conditioned in chemistry one year is allowed in which to remove the condition. The laboratories and lecture rooms offer ample facilities, and the equipment is good; special facilities are open to those desiring to pursue advanced or original work. The course of study covers four years of nine months each; the course is graded, and each correlated group as taken up presents sufficient variety to avoid monotony. A series of written, oral and practical examinations are distributed throughout the course of study. Fees: Matriculation, $5; $200 each year. The Dean is Dr. William L. Richardson, 688 Boylston St. The total registration for 1904-5 was 307; graduates, 67. The 124th session begins Sept. 28, 1905, and ends June 28, 1906.

TUFTS COLLEGE MEDICAL SCHOOL.—This school was organized in 1893 as the Medical Department of Tufts College. It has a faculty of 33 professors, 55 assistants and lecturers, etc., a total of 88. Clinical material is furnished by the Boston City Hospital, Massachusetts Charitable Eye and Ear Infirmary, Free Home for Consumptives, Free Hospital for Women; Boston Dispensary, Cambridge Hospital, St. Elizabeth's Hospital, Carney Hospital and the college dispensary; the student has also [illegible] from an out-department in connection with [illegible] "Graduates of a high school, college or [illegible] having certificates of entrance to a college or university, or holding the State of New York [illegible] so certain approved preparatory school grad[illegible]thout examination; all others must pass an [illegible] Latin, physics and mathematics, including e[illegible] plane geometry. The laboratories and lecture [illegible] heir equipment and capacity. Teaching is carried on by means of lectures, recitations and practical work in the laboratories and clinics; frequent examinations are held during a course, and final examination on completing the subject. Graded instruction covering four years of eight months each makes up the full course. The total fees are $150 each year; dissecting material is furnished at cost. The Dean is Dr. Harold Williams. Total number of students for 1904-5 was 385; graduates, 62. The twelfth session begins Sept. 27, 1905, and ends May 30, 1906.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1880, and has a faculty of 25 professors and 14 lecturers and assistants, a total of 39. Clinical facilities are furnished by the North End Dispensary Hospital, Union General Hospital, and the city and state institutions. This school is a member of the Association of American Medical Colleges. The course of study covers graded work for four years of nine months each. The total fees for the first year are $100, and for each of the other years about $110, with a graduation fee of $30. The Registrar is Dr. John H. Jackson, 155 Franklin St., Fall River. Total students registered, 1904-5, 168; graduates, 28. The twenty-sixth session begins Sept. 19, 1905, and ends June 18, 1906.

BOSTON UNIVERSITY SCHOOL OF MEDICINE.—Homeopathic. This school was organized in 1873; in 1874 the New England Female Medical College, founded in 1848, was merged into it. The faculty includes 20 professors, 39 associates and assistants, etc., a total of 59. Clinical material is furnished by the Massachusetts Homeopathic Hospital, containing 235 beds, a dispensary, a maternity hospital, and the Westborough Insane Hospital, 800 patients. Candidates who have taken their degree in arts, philosophy or science are not examined; certificates of graduation from approved high and preparatory schools accepted in lieu of entrance examinations; all others are examined in English, Latin, French or German, or history, mathematics, physics and chemistry. The instruction is graded and covers a period of four years, eight months each. Total fees for the first year are $105; for the second and third, $125 each, and for the last year, $155. The Dean is Dr. John P. Sutherland, 295 Commonwealth Ave. Total registration for 1904-5 was 93; graduates, 14. The thirty-third session opens Oct. 5, 1905, and closes June 6, 1906.

MICHIGAN.

Michigan, population 2,420,982, has six medical colleges. Two of these, University of Michigan, Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a city of about 16,000 people. Board and lodging cost from $2.50 to $5 a week. Detroit, a city of 300,000 inhabitants, contains three medical colleges, as follows: Detroit College of Medicine, Detroit Homeopathic College and the Michigan College of Medicine and Surgery. Board and room can be obtained for $3 a week and upward. Grand Rapids Medical College is located in Grand Rapids, population 87,565. Room and board cost from $3 to $3.50 a week.

Ann Arbor.

UNIVERSITY OF MICHIGAN, DEPARTMENT OF MEDICINE AND SURGERY.—This was organized in 1850, and has a faculty composed of 18 professors, 35 associates, instructors, etc., a total of 53. The University Hospital, with nearly 200 beds, furnishes the clinical facilities. The requirements for admission provide that the applicant, either by certificate or examination, show a sufficient knowledge of the following: English grammar, rhetoric and composition; United States and general history; algebra, through quadratics, plane and solid geometry and plane trigonometry; physics, biology and chemistry, these subjects to be accompanied by laboratory work; German or French and Latin. The laboratories and their equipment are good, and the training in them and in didactic work is thorough. The new medical building accommodating the laboratories of hygiene, bacteriology, physiologic chemistry, pathology, histology, embryology and anatomy is now completed and occupied. This school is a member of the Association of American Medical Colleges. The curriculum embraces four years of nine months each. A combined course leading to degrees in both arts and medicine in six years is offered. The total fees for Michigan students for the entire course of four years is about $300, and for others $350. The Dean is Dr. Victor C. Vaughan. Total registration for 1904-5 was 376; graduates, 61. Next session begins Sept. 26, 1905, and will end June 21, 1906.

HOMEOPATHIC COLLEGE, UNIVERSITY OF MICHIGAN.—This department of the University was organized in 1875, and has a faculty of 29 professors and 20 assistants, total 49; a part of the teaching force is from the other departments of the University. The Homeopathic Hospital, containing 140 beds, furnishes material for clinical teaching. The course covers four years of nine months each. The total fees for Michigan students are about $240 for the four years, and for other students about $295. The Dean is Dr. W. B. Hinsdale. The enrolment for 1904-5 was 66; graduates, 12. The next session begins Sept. 26, 1905, and closes June 21, 1906.

Detroit.

DETROIT COLLEGE OF MEDICINE.—This school was formed in 1885 by the union of Detroit Medical College organized in 1868, and the Michigan College of Medicine, established 1880. The faculty embraces 21 professors, 71 lecturers, instructors, etc., a total of 92. Clinical facilities are offered by the following hospitals: St. Mary's and Harper, each of which contain a free dispensary; Woman's, St. Luke's, the Children's Free Hospital and the House of Providence. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The work includes laboratory, didactic and clinical study. Fees: Matriculation, paid once, $5; tuition, each term, $65; hospital and laboratory tickets, each $10, and diploma fee, $30. The Secretary is Dr. H. O. Walker. Total enrolment for 1904-5 was 208; graduates, 54. The next session begins Sept. 20, 1905, and will close May 3, 1906.

MICHIGAN COLLEGE OF MEDICINE AND SURGERY—SAGINAW VALLEY MEDICAL COLLEGE.—These two schools, organized in 1888 and 1896, respectively, were consolidated last year, to continue on the site of the former. The faculty numbers 57. Clinical facilities are offered by a college dispensary, the Emergency Hospital and Detroit Eye and Ear Infirmary. This school is a member of the Association of American Medical Colleges. The course covers graded work for four years of eight months each. The fees are about $80 to $95 per year; third year, $70, and $95 for the fourth year. The Dean is Dr. Hal. C. Wyman, 46 W. Adams Ave., Detroit. Total registration for 1904-5 was 78; graduates, 26. The next session begins Sept. 19, 1905, and will end May 8, 1906.

DETROIT HOMEOPATHIC COLLEGE.—This was organized in 1899, and has a faculty of 37. Grace Hospital and a college dispensary are available for study of clinical cases. Unless possessing at least a high school diploma applicants for admission will be examined by the state board. The course embraces work for four years of eight months each. Fees: From $70 to $90 per year. The Dean is Dr. D. A. MacLachlan; Registrar, J. M. Griffin. Total enrolment for 1904-5 was 44; graduates, 12. The next session begins September, 1905, and will close May, 1906.

Grand Rapids.

GRAND RAPIDS MEDICAL COLLEGE.—This was organized in 1897. The faculty is made up of 27 professors and 6 assistants, in all 33. Clinical cases in the U. B. A., St. Mary's and Woman's Butterworth hospitals and St. John's Orphan Asylum and a college dispensary are available for study. The course is four years of seven months each. The total fees are about $65 for each year. The Dean is Dr. G. L. McBride, 141 E. Bridge St. Next session opens Sept. 27, 1905, and closes May 1, 1906.

MINNESOTA.

Minnesota, population 1,751,394, contains three medical colleges: Hamline University College of Medicine, and the two medical departments of the University of Minnesota, viz., the College of Medicine and Surgery and the College of Homeopathic Medicine and Surgery. They are all situated in Minneapolis, a city with a population of 225,000. The various hospitals of Minneapolis furnish ample clinical material, and owing to the proximity to St. Paul the clinical advantages of that city are available. The average cost of board and lodging is $20 a month.

Minneapolis.

COLLEGE OF MEDICINE AND SURGERY, UNIVERSITY OF MINNESOTA.—This department of the University of Minnesota was created in 1883, but at that time its only function was to examine for the degrees of B.M. or M.D. In 1888, by the consolidation and absorption of the Minnesota Hospital Medical College and the St. Paul Medical College, its present status was assumed. The faculty is composed of 30 professors and 75 [illegible] assistants, a total of 105. The medical school [illegible] and its laboratories are excellent. Eight [illegible] Twin Cities, beside the University Dispensary and St. Paul dispensary, afford an abundant supply of material for clinical study. The curriculum covers four years of nine months each, and the work is carefully graded. The entrance requirement of one year of university, in addition to four years of high school work, limits the number of students, but assures a high standard of the student body. This school is a member of the Association of American Medical Colleges. Total number of students registered in 1904-5 was 227; graduates, 75. Total fees for each year, $100. The Dean is Dr. Parks Ritchie. The next session opens Sept. 1, 1905, and closes June 1, 1906.

COLLEGE OF HOMEOPATHIC MEDICINE AND SURGERY.—This is a department of the University of Minnesota and was organized in 1888. The faculty comprises 19 professors and 14 assistants, 33 in all. Instruction in the primary branches is received, in common with the students of the College of Medicine and Surgery from the professor of the department of medicine. The course is graded, extending over four years of nine months each. The total fees for the first two years are $100 each and $80 each for the last two years. The Dean is Dr. Eugene L. Mann. Total number of students registered in 1904-5 was 16; graduates, 4. The next session opens Sept. 1, 1905, and closes June 1, 1906.

HAMLINE UNIVERSITY COLLEGE OF MEDICINE.—This was organized in 1883. Its faculty is composed of 29 professors, 16 instructors and assistants, a total of 45. The laboratories and lecture rooms are large, well lighted and supplied with all the necessary [illegible] is offered to the student in City Hospital, [illegible] d, Swedish, St. Barnabas' and St. Mary's [illegible] Luther Hospital, City and County, and [illegible] and the college dispensary. This school belongs to the Association of American Medical Colleges. The course of study covers graded work for four years, eight and a half months making a year. Total fees, first year, $90; second year, $87.50, and for each of the last two, $80. The Dean is Dr. George C. Barton. Total number of students, 1904-5, was 123; graduates, 10. The next session begins Sept. 19, 1905, and ends June 6, 1906.

MISSISSIPPI.

Mississippi, population 1,551,270, has one medical college, the Medical Department of the University of Mississippi, located at Oxford, a city with 2,000 inhabitants.

Oxford.

UNIVERSITY OF MISSISSIPPI MEDICAL DEPARTMENT.—This school was organized two years ago, with 7 professors and 5 assistants, a total of 12. Each college term extends over nine months. The school is a member of the Association of American Medical Colleges. Dr. W. S. Leathers is the Acting Dean. The total registration in 1904-5 was 18; graduates, none. The next session begins Sept. 21, 1905, and ends June 7, 1906.

MISSOURI.

Missouri, population 3,106,665, has eleven medical colleges. St. Louis, population 575,238, contains six of these, viz.: St. Louis College of Physicians and Surgeons, American Medical College, Homeopathic Medical College of Missouri, Medical Department St. Louis University, (Marion-Sims-Beaumont College of Medicine), Washington University Medical Department, and Barnes Medical College. Board and lodging can be procured for from $3.50 to $5 a week. Kansas City, with 163,752 inhabitants, has six colleges, namely: Kansas City Medical College, University Medical College, the Hahnemann Medical College of Kansas City, Medico-Chirurgical College and Eclectic Medical University. Room and board can be obtained in this city for from $3 to $5 a week. Ensworth Medical College and Central Medical College are located in St. Joseph, population 105,000; board and room can be had for from $3.50 to $5 a week. Department of Medicine of the University of Missouri is at Columbia, a town of 5,651. Board and lodging can be obtained at Columbia for from $2 to $5 a week. (Since writing the above, the Kansas City Medical College and the Medico-Chirurgical college have been absorbed by the University of Kansas, and the Ensworth and Central Medical colleges have united.)

Columbia.

DEPARTMENT OF MEDICINE OF THE UNIVERSITY OF MISSOURI.—This department was organized at Columbia in 1872. The faculty includes 11 professors, 19 assistant professors, lecturers, etc., a total of 30. Clinical facilities are supplied by the Parker Memorial State Hospital. A new $40,000 building for the medical laboratories has recently been completed and [illegible] nt. Special emphasis is laid on thorough trai[illegible] ranches which constitute the foundation of [illegible] course nine months each, carefully graded. The university offers also a combined course of six years, conferring degrees in both arts and medicine. The entrance requirements are a diploma from a good high school, or the full equivalent. This school is a member of the Association of American Medical Colleges. There is no charge for tuition, the only expenses being a library fee of $10 each year, and small laboratory fees. The Dean is Dr. A. W. McAlester. Total registration of students for 1904-5 was 108; graduates, 8. The next session opens Sept. 12, 1905, and closes June 6, 1906.

Kansas City.

UNIVERSITY MEDICAL COLLEGE.—This was organized in 1881 as the University of Kansas City Medical Department, and in 1888 was reorganized under its present name. Its faculty comprises 37 professors and 48 lecturers and assistants, a total or 85. *Clinical* material is furnished by the University Hospital, owned by the college, with 100 beds; the City Hospital, German Hospital, Home for the Aged, containing 147 beds; the Sisters' Hospital, Scarritt and St. Margaret's hospitals, the Children's Home, St. Joseph's Orphan Asylum, and the college dispensary and obstetric department. Instruction is given by means of lectures, recitations, demonstrations and laboratory work and clinics. The school is a member of the Association of American Medical Colleges. The college building, which has been recently enlarged, furnishes ample accommodations for laboratories and lecture rooms. The course of study covers four years of 30 weeks each, and the work is graded. The total fees for each of the first two years are $100; for the third, $80, and $100 for the fourth year. The Dean is Dr. Samuel C. James, Bryant Bldg. The total number of students registered in 1904-5 was 238; graduates, 58. The twenty-fourth session begins Sept. 5, 1905, and ends April 20, 1906.

KANSAS CITY MEDICAL COLLEGE.—This school was established in 1869, and in 1905 was absorbed by the University of Kansas, becoming the clinical department of the University. The first two years of the course will probably be taught in Lawrence, Kan., the last two in Rosedale, Kan., and Kansas City, Mo. The total registration for 1904-5 was 116; graduates, 34.

MEDICO-CHIRURGICAL COLLEGE.—This school was organized in 1897 as the Kansas City College of Medicine and Surgery, and was reorganized in 1898 under the above name. In 1905 the college became the clinical department of the University of Kansas, together with the Kansas City Medical College and the College of Physicians and Surgeons of Kansas City, Kan. The total registration for 1904-5 was 38; graduates, 12.

KANSAS CITY HAHNEMANN MEDICAL COLLEGE.—This school was formed by the union of the Kansas City Homeopathic Medical Col[illegible] nsas City University College of [illegible] It has a faculty of 43. The [illegible] tal, the Sanitarium Scarritt, [illegible] German, Bethany and Child[illegible] dents for clinical study. The [illegible] upply clinical material. Applicants for admission must show by diploma, certificate or examination that they have a sufficient knowledge of English, arithmetic, geography, United States history and Latin equal to one year's work. The course covers four years of seven months each. The Dean is Dr. Moses T. Runnels, 912 Walnut St. Total registration for 1904-5 was 32; graduates, 9. The next session begins September 5, 1905, and closes April 1, 1906.

ECLECTIC MEDICAL UNIVERSITY.—This was organized in 1898, and has 25 in its faculty. The curriculum covers four years of eight months each. Fees, about $70 each year, with a graduation fee of $15. The Dean is Dr. Theodore Doyle. Total students for 1904-5 was 56; graduates, 17. The next session begins Sept. 11, 1905, and ends April 22, 1906.

HOMEOPATHIC MEDICAL COLLEGE OF MISSOURI.—This was organized in 1857, and has a faculty of 33 professors and 5 assistants, total, 38. The curriculum covers four years of seven months each. Fees: First year, $80; second, $75, third, $60, and $85 for the fourth year. The Dean is Dr. L. C. McElwee, 1221 North Grand Ave., St. Louis. Total registration for 1904-5 was 45; graduates, 7. The next course begins Sept. 10, 1905, and ends April 15, 1906.

St. Joseph.

ENSWORTH MEDICAL COLLEGE.—This was organized in 1873 and has a faculty of 25 professors and 7 lecturers and assistants, 32 in all. Ensworth Hospital, with 250 beds; City Hospital, containing 40 beds; the State Hospital, No. 2, which is open to the students once a week, and a college dispensary furnish clinical material. Applicants for admission must show by certificate or examination that they possess a sufficient knowledge of English, arithmetic, algebra, physics and Latin equal to one year's instruction. The building furnishes ample laboratory and lecture-room facilities. The curriculum covers a graded course of four years of seven months each. The fees are about $55 each for the first three years, and $75 for the fourth year. The Secretary is Dr. J. W. Heddens, 614 Francis St. Total enrolment for 1904-5 was 90; graduates, 22. The next session opens Sept. 15, 1905, and closes April 20, 1906. (This school united with the Central Medical College in 1905, assuming the name of Ensworth-Central Medical College.)

CENTRAL MEDICAL COLLEGE.—This schoo[illegible]
and has a f[illegible] 1 10

C. A. Tygart. Total enrolment for 1904-[illegible]
The next session begins Sept. 15, 1905, and will end April 15, 1906. (College now united with Ensworth Medical College.).

St. Louis.

WASHINGTON UNIVERSITY MEDICAL DEPARTMENT.—This school was organized in 1891 from the St. Louis Medical College, which was founded in 1842. In 1899 the Missouri Medical College, organized in 1840, was added. The f[illegible] ssors, 35 lecturers and instructors, a tot[illegible] ial is [illegible] Louis Mullan[illegible] Uni[illegible] Dispensary, [illegible] Lying-[illegible] Hospital and O'Fallon Dispensary. In addi[illegible] tion to these, [illegible] Hospital and Insane Asylum are used in common with the other schools. The Medical Department is a member of the Association of American Medical Colleges. The college buildings, of which there are two, furnish the best laboratory and lecture-room facilities. The course is four years of eight months each, and the system of study embraces laboratory, didactic and clinical teaching. The total fees for the first year are $126.25; second, $120.25; and for the third, $106.25, and fourth, $101.25. The Dean is Dr. Robt. Luedeking. Total registration of students for 1904-5 was 263; graduates, 64. The next session opens Sept. 29, 1905, and closes May 24, 1906.

ST. LOUIS UNIVERSITY MEDICAL DEPARTMENT (MARION-SIMS-BEAUMONT COLLEGE OF MEDICINE).—This is the Medical Department of the St. Louis University. The faculty is composed of 42 professors, 63 lectu[illegible] a total of 105. Clinical facilities are offered [illegible] or
Rebekah Hospital, [illegible]
Hospital, 50 beds; [illegible] ls,
beds; Good Samari[illegible] and Insane Asylum, each
containing 150 beds, [illegible]

with a capacity of 600 patients. Grand Avenue Dispensary also furnishes good material for practical instruction. This school is a member of the Association of American Medical Colleges. The buildings afford ample laboratory and lecture-room space, and they are well equipped. The course of study embraces laboratory and clinical instruction, with recitations and lectures. The curriculum covers four years of seven months each. The total fees for the first year are $80; for the second and third, $75 each, and $100 for the fourth. The Secretary is Dr. H. W. Loeb, 3559 Olive St. Total number of students registered for 1904-5 was 385; graduates, 103. The next session opens Oct. 1, 1905, and closes May 1, 1906.

ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1878, and has a faculty of 24 professors, 15 lecturers, instructors, etc., a total of 39. The resources for clinical instruction are Jefferson Hospital, which is open to students of this college only; City Hospital, with 600 beds: Female Hospital, having 250 beds; City Insane Asylum; City Poorhouse, and the college dispensary. This college is a member of the Association of American Medical Colleges. The laboratory and lecture-room space and the equipment are ample. The course of study covers four years of seven months each, and is graded. Total fees for the first year are $80; second, $70; third, $75, and $85 for the fourth year. The Dean is Dr. Waldo Briggs, 2600 Gamble St. Total number of students registered, 1904-5, was 275; graduates, 29. The next session begins Sept. 15, 1905, and ends April 12, 1906.

BARNES MEDICAL COLLEGE.—(Medical Department Barnes University.) This school was organized in 1892, and has a faculty of 35 professors and 25 lecturers and assistants, a total of 60. The clinical advantages are those offered by Centenary Hospital, with 150 beds; City Hospital, the college dispensary and the outdoor obstetrical department. The laboratories are well equipped and other facilities ample. The course of study includes graded work for four years of seven months each. The total fees for the first three years are $75 each year, and $85 for the fourth year. The Secretary is Dr. Pinckney French, Missouri Trust Building. Total registration for 1904-5 was 427; graduates, 109. The next session opens Sept. 17, 1905, and closes May 10, 1906.

AMERICAN MEDICAL COLLEGE.—Eclectic. This was organized in 1873, and has a faculty of 17 professors. St. Louis City Hospital and a college dispensary supply ample clinical material. The requirements for admission are those of the National Federation of Eclectic Medical Colleges of which this college is a member. The course of study covers four years of seven months each. The total fees are: Tuition, $75 per year, dissecting material $5 per year for four years, final examination and graduation fee $25. Total registration for 1904-5 was 66; graduates, 16. The Dean is Dr. M. M. Hamlin, 2906 Lawton Avenue. The next session opens Sept. 18, 1905, and closes April 22, 1906.

NEBRASKA.

Nebraska, population 1,066.300, has three medical colleges: The University of Nebraska College of Medicine and John A. Creighton Medical College of Omâha (population 102,555); and Lincoln Medical College, at Lincoln (population 40,169). Board and lodging can be obtained for from $3 to $5 a week.

Lincoln and Omaha.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE.—This was organized in 1880 as the Omaha Medical College. In 1902 an affiliation was entered into with the University of Nebraska, the name being changed to the College of Medicine of the University of Nebraska. The first two years are given at Lincoln. The last two years are given only at Omaha. The faculty is composed of 38 professors and 22 lecturers and assistants, total 60. The Douglas County, Immanuel, Wise Memorial and Omaha Methodist hospitals, together with the college dispensary, furnish an abundance of material for clinical study and demonstration. The course consists of graded studies covering four years of eight months each. The method of instruction consists of didactic and clinical lectures, section clinics, demonstrations, recitations and laboratory work. The college building is well adapted to its purpose, the laboratories being well equipped and the lecture room commodious. The fees, including breakage deposits, are $90 for the first two years, and $100 for the last two years. Total number of students enrolled in 1904-5, 92; graduates, 28. The college is a member of the Association of American Medical Colleges. The Secretary is Dr. Paul H. Ludington, Bee Building. The next annual session will begin Sept. 19, 1905, and end May 24, 1906.

Omaha.

JOHN A. CREIGHTON MEDICAL COLLEGE.—This school, organized in 1892, is the Medical Department of Creighton University, and has a faculty c associates lecturers and assistants, a tota ilities are those of St. Joseph's Hospital, having a clinical amphitheater connected Hospital, with 256 beds: Douglas County and Mercy hospitals, and the college dispensary; the material is abundant and varied. The school is a member of the Association of American Medical Colleges. The building, which was completed in 1898, contains excellent facilities for laboratory and lecture-room work, and the equipment is good. In the methods of instruction, including clinical, didactic and laboratory work, special emphasis is laid on practical work. The course of study embraces four years of eight months each. The total fees for the first two years are $90 each, and $85 for each of the last two years. The Dean is Dr. D. C. Bryant, McCague Bldg. Total number of students registered in 1904-5 was 167; graduates, 34. The thirteenth session opens Sept. 19, 1905, and closes May 1, 1906.

Lincoln.

LINCOLN MEDICAL COLLEGE.—Eclectic. This was organized in 1889, and has a faculty of 28. The requirements for admission are those of the National Confederation of Eclectic Medical Colleges, of which this college is a member. The course of study covers four years of thirty-two weeks each. The total fees for the first year are $80; second, $75; third, $75, and $85 for the fourth year, or $255 for all four years together. The Secretary is Dr. Samuel Metheny. Total number of students for 1904-5 was 81; graduates, 15. The next session begins Sept. 13, 1905, and ends April 20, 1906.

NEW HAMPSHIRE.

New Hampshire, population 411,588, contains one medical college, located in Hanover, population, 1,884.

Hanover.

DARTMOUTH MEDICAL SCHOOL.—This is the Medical Department of Dartmouth College, and was organized in 1797. Its faculty is made up of 18 professors and 2 instructors, 20 in all. The Mary Hitchcock Memorial Hospital, a cottage hospital of 36 beds, supplies the clinical material. Applicants for admission must possess an education at least equivalent to graduation from a registered high school. The laboratories afford good facilities for work. The course covers four years of thirty-two weeks each. Fees: $100 each year. The Dean is Dr. William T. Smith. The total number of students registered for 1904-5 was 60; graduates, 12. The work for the first and second years begins with that of the academic department, commencing Sept. 21, 1905, and closing June 27, 1906; for the advanced classes it begins Aug. 15, 1905, and ends March 30, 1906.

NEW YORK.

New York State, population 7,268,894, has ten medical colleges. Seven of these, College of Physicians and Surgeons, Columbia University, Long Island College Hospital, New York Homeopathic Medical College and Hospital, New York Medical College and Hospital for Women, Eclectic Medical College of the City of New York, Cornell University Medical College and the University and Bellevue Hospital Medical College, are located in New York City, population 3,437,202. This city, with its hospitals and dispensaries, offers abundant clinical material. Board and lodging can be obtained for from $5 to $7 a week.

Albany Medical College is in Albany, a city of 100,000 people, where board and room can be had for from $4 to $5 a week.

The University of Buffalo Medical Department is situated in Buffalo, population 352,387; here board and lodging can be obtained for from $3.50 to $5 per week.

The College of Medicine, Syracuse University, is in Syracuse, a city of 18,374 inhabitants. Board and lodging can be obtained for from $3.50 a week upward.

The laws of the State of New York require of the prospective student of medicine a preliminary education equivalent to that obtainable in a four years' course in any of the public high schools recognized by the regents as maintaining a satisfactory standard. On proof of at least this amount of education, a medical-student certificate will be issued by the state authorities. Certain medical schools of the state have additional requirements.

1. The College of Physicians and Surgeons requires a medical-student certificate issued on the attendance of at least one year's course of study in a college or scientific school registered by the Regents as maintaining a satisfactory standard (or equivalent) or a certificate of the college entrance examination board covering 15 points, each point being the equivalent of a course of five periods weekly throughout the academic year.

2. Cornell University Medical College requires Regents' counts; in algebra 4 counts, plane geometry 4, elementary United States history and civics 2, second year English or its equivalent 8, second year Latin or the first four books of Caeser's Commentaries, or first year Latin and first year German or French or Spanish 8, making a total of 26 counts, with additional counts aggregating 48 counts.

3. University and Bellevue Hospital Medical College requires unconditional matriculation with a medical-student certificate.

4. The College of Medicine, Syracuse University, requires Regents' counts; in Latin 4 counts, plane geometery 4, algebra 2 and inorganic chemistry 2, with additional, aggregating 48 counts.

New York City.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1807 and its present relation, that of Medical Department of Columbia University, was assumed in 1860. The faculty embraces 33 professors and 95 demonstrators, instructors, etc., a total of 128. The Vanderbilt Clinic, where 42,995 patients were treated during the year 1904, and which is equipped with all modern appliances for the study and treatment of disease, and Sloane Maternity Hospital, containing 124 beds, offer exclusive clinical advantages to students of this school. Beside these, Roosevelt Hospital, containing 244 beds; New York Hospital, with 190 beds; Bellevue, 1,100 beds; Presbyterian, 330 beds; St. Luke's, 225 beds; General Memorial, 100 beds, and New York Foundling Hospital, 700; Willard Parker and Reception and Riverside hospitals, 600 beds; Babies' Hospital, 50 beds; St. Mary's Free Hospital for Children, 120 beds, all offer free clinical teaching to matriculants of this school. The laboratories, lecture rooms and amphitheaters are ample in equipment and accommodation; special provisions are made to equip each student thoroughly in each of the laboratories and thus make the work individual. The work is graded, covering four years of eight months each. The Dean is Dr. Samuel Lambert. The total fees for the first year are $255; for the second and third, $250, and $275 for the fourth year. Total registration for 1904-5 was 568; graduates, 178. The next session begins Sept. 27, 1905, and ends June 13, 1906.

Long Island College Hospital.—This was organized in 1858 and has a faculty of 20 professors and 75 assistants, instructors, etc., a total of 95. Long Island College Hospital, containing 300 beds and connected with a four-story maternity hospital; Polhemus Memorial Clinic, Dudley Memorial and Hoagland Laboratory, completely equipped with the most modern apparatus, are all a part of the college. Beside the clinical facilities furnished by these, members of the faculty attend at Kings County, St. John's, Brooklyn, Norwegian, Williamsburg, Methodist Episcopal and the Brooklyn Eye and Ear hospitals, where the students are offered opportunities for clinical study. Many of these also contain out-patier [illegible]; permitting advanced students to attend [illegible] Bedside instruction is also given in the wards [illegible] four years of thirty weeks each. Fees: First year, $195; second, $200; third, $160, and $195 for the fourth year. The Secretary is Dr. Joseph H. Raymond. Total registration, 1904-5, was 414; graduates, 73. The forty-eighth session opens Oct. 2, 1905, and closes June 2, 1906. The summer session has been discontinued owing to the lengthening of the regular session.

Cornell University Medical College.—This department of Cornell University was established in 1898. The faculty is composed of 45 professors and 162 instructors and assistants, a total of 207. The City Hospital, having 1,000 beds; Bellevue Hospital, New York Hospital, Presbyterian, Willard Parker and Reception with 200 beds; New York Skin and Cancer; St. Francis, having a capacity of 230 beds; St. Vincent's, with 200 beds; the Manhattan Eye and Ear Infirmary, in addition to a large college dispensary, furnish the clinical resources; the material is abundant and varied. The first two years of the course are taken at New York or at Ithaca, and the work is devoted to the fundamental scientific subjects. The last two years are spent mostly in practical and clinical work and the hospital advantages are utilized. The Loomis Laboratory, a five-story modern building, is well equipped and supplies ample practical laboratory facilities required in the advanced work. "The essential features of the entire system is the division of the classes of the several years into small sections." Fees: First year, $190; second and third, $180 each, and $200 for the fourth year. The Dean is Dr. William M. Polk. Total registration for 1904-5 was 392; graduates, 74. The next session opens Sept. 27, 1905, and closes June 13, 1906.

University and Bellevue Hospital Medical College.—This is a department of the New York University, and was founded in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. The faculty is composed of 39 professors and 64 instructors, assistants, etc., in all 103. Bellevue and City hospitals, hospitals of the Workhouse and Almshouse, Manhattan State Hospital for the Insane, Willard Parker and Reception hospitals, Riverside Hospital for Contagious Diseases, Randall's Island, Presbyterian, St. Luke's, St. Vincent's, General Memorial, Gouverneur, Columbus, Harlem, New York Foundling, and the Society for the Lying-in hospitals, the New York Eye and Ear Infirmary, and a large college dispensary are open to students of this school for a study of clinical cases. The Carnegie building, a five-story structure adjoining the college, is devoted to laboratory instruction and investigation, and, with the other two large college buildings, affords good laboratory and lecture-room facilities. A new six-story addition to the laboratory building has just been completed. The course of instruction covers four years of eight months each. Actual clinical teaching, in conjunction with and found on laboratory work, recitation and didactic teaching, is emphasized to the greatest possible degree. Fees: First year, $185; second and third, $180 each, and $195 for the fourth year. The Dean is Dr. Edward G. Janeway. Total registration for 1904-5 was 391; graduates, 47. The next session opens Oct. 4, 1905, and closes June 9, 1906.

New York Homeopathic Medical College and Hospital.—This school, organized in 1858, has a faculty of 33 professors and 44 lecturers, instructors, etc., 77 in all. Flower Hospital, adjoining the college and having a completely equipped out-patient department: Metropolitan Hospital, New York Ophthalmic Hospital and the Laura Franklin Free Hospital for Children also furnish clinical facilities. The course covers four years of seven months each. Total fees for the first year, $130; second, $130; third, $125, and $155 for the fourth year. The Dean is Dr. W. H. King, 64 W. 51st St. Total students registered for 1904-5 was 110; graduates, 23. The next session begins Oct. 4, 1905, and ends May 17, 1906.

New York Medical College and Hospital for Women.—Homeopathic. This school was organized in 1863, and has a faculty of 22 professors, 19 lecturers and assistants, total 41. The college hospital and dispensary, the Memorial Hospital for Women, Metropolitan, Ophthalmic and the Laura Franklin Free Hospital for Children afford clinical material. The course covers four years of twenty-six weeks each. Fees: First year, $145; second, $140; third, $135, and $155 for the fourth year. The Dean is Dr. M. Belle Brown, 30 W. 51st St. Total registration for 1904-5 was 34; graduates, 9. The next session opens Oct. 2, 1905, and closes May 9, 1906.

Eclectic Medical College of the City of New York.—This was organized in 1865, and has a faculty of 15 professors and 19 lecturers, demonstrators, etc., 34 in all. A college dispensary, Beachonian Dispensary, Manhattan and Red Cross hospitals and Muncie Sanatorium supply clinical facilities. The work covers four years of seven months each. The total fees: First year, $125; second, $125; third, $125, and $155 for the fourth year. The Dean is Dr. George W. Boskowitz. Total registration for 1904-5 was 99; graduates, 13. The next session opens Sept. 27, 1905, and closes May 1, 1906.

Albany.

Albany Medical College.—This school was organized in 1838, and in 1873 it assumed its present relations, as Medical Department of Union University. The faculty is composed of 15 professors and 57 lecturers, instructors and assistants, a total of 72. Albany, St. Peter's, Child's and County hospitals, South End Dispensary, Eye and Ear Infirmary and the Albany Hospital for Incurables, also the free dispensaries connected with each, are open to students for clinical study. The curriculum embraces graded work for four years of seven and one-half months each. Teaching is carried on in the laboratories, clinics and lecture rooms. Examinations are held twice a year in all subjects. Fees: Third year, $110, and $130 for each other year. The Dean is Dr. Samuel B. Ward. Total registration for 1904-5 was 172; graduates, 52. The next annual session opens Sept. 26, 1905, and closes May 8, 1906.

Buffalo.

University of Buffalo Medical Department.—This was organized in 1846 and has a faculty made up of 46 professors and 36 assistants, lecturers, etc., a total of 82. Buffalo General Hospital, Hospital of the Sisters of Charity, Erie County and German hospitals and the German Deaconess' Hospital supply ample clinical material for study. A college dispensary, recently organized, is also of value in practical work. The buildings and hospitals are well equipped for clinical and laboratory work. Bedside instruction is insisted on and the senior students are permitted to assist in operations and give anesthetics. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The tuition is $125 each year; this does not include laboratory fees. The Dean is Dr. Matthew D. Mann, 37 Allen St. Total registration for 1904-5 was 231; graduates, 37. The sixtieth session opens Sept 25, 1905, and closes May 31, 1906.

Syracuse.

College of Medicine, Syracuse University.—This school was organized in 1872 as the Medical Department of Syracuse University. The faculty is composed of 15 professors and 39 lecturers, instructors, etc., in all 54. Clinical facilities are furnished by St. Joseph's Hospital, with a capacity of 200 patients; Hospital of the House of the Good Shepherd, Syracuse Hospital for Women and Children, Onondaga County Orphan Asylum, and the Syracuse Free Dispensary. The laboratories and amphitheaters are large and well equipped. This school is a member of the Association of American Medical Colleges. The curriculum embraces a four years' graded course, eight months making a school year. The total fees for each of the four years are $130. Beginning with the session of 1905-6, additional laboratory and graduation fees will be required, making the average total fee for each year $167.25. The Dean is Dr. Henry D. Didama, 424 S. Salina St. Total number of students registered for 1904-5 was 154; graduates, 31. The next session opens Oct. 3, 1905, and closes June 13, 1906.

NORTH CAROLINA.

North Carolina, population 1,893,810, has four medical schools which grant degrees and one which gives only the first two years of the medical course. The Medical Department of the University of North Carolina is located at Chapel Hill (population 1,099) and at Raleigh (population 13,643). The Leonard School of Medicine is at Raleigh. The North Carolina Medical College is located at Davidson (population 904), and at Charlotte (population 18,000). Wake Forest School of Medicine is at Wake Forest (population 823).

Chapel Hill and Raleigh.

University of North Carolina Medical Department.—This school was organized in 1891, and formerly gave only the work of the first two college years at Chapel Hill. In 1902 the course was extended to four years by the establishment of a department at Raleigh, in which the last two years are given. Degrees are now conferred and the faculty in the completed school of medicine numbers 29. It is a member of the Association of American Medical Colleges. The number of students enrolled in 1904-5 was 100; graduates, 11. Total fees are $85 per year. Board, room, light and heat may be had from $84 to $102 per college year. The President is Dr. F. P. Venable, Chapel Hill. The next session will begin Sept. 11, 1905, and end June 6, 1906.

Raleigh.

Leonard School of Medicine.—Colored. This department of Shaw University was established in 1882 by the American Baptist Home Mission Society to train colored students of medicine. It has a faculty of 10. A free hospital and dispensary supply clinical material. A preliminary entrance examination is given to applicants not possessing a certificate or diploma of educational requirements. The course covers four years of seven months each. The total fees for each year are $75. The dormitory plan is adopted generally, and board and room costs $2 a week. The Dean is Dr. James McKee. Total enrolment for 1904-5 was 136; graduates, 21. Next session opens Oct. 1, 1905, and closes April 14, 1906.

Davidson and Charlotte.

North Carolina Medical College.—This school was organized in 1893, and has a faculty of 21. The Presbyterian Hospital in Charlotte supplies the clinical facilities. The course covers four years of eight months each; the last year at Charlotte. Fees: First three years, $85 each, and $100 for the fourth year. The President is Dr. J. P. Monroe of Davidson; Dr. I. W. Faison, Charlotte, is Dean of the Faculty. The total registration for 1904-5 was 81; graduates, 26. The next session begins Sept. 7, 1905, and closes April 2, 1906.

Wake Forest.

Wake Forest School of Medicine.—This school was organized in 1902. It only gives the first two years of the medical course. Each annual course extends over nine months. The school is a member of the Association of American Medical Colleges. It has a faculty of 10, and last year enrolled 18 students. The fees are $85 a year. The Dean is Dr. Frederick K. Cooke. The next session opens Aug. 31, 1905, and closes May 26, 1906.

OHIO.

Ohio, population 4,157,545, has ten medical colleges. Four of these, the Medical College of Ohio, Eclectic Medical Institute, Miami Medical College, and Pulte Medical College are located in Cincinnati, a city of 325,902 inhabitants. The clinical advantages of Cincinnati are good; beside many smaller hospitals, the Cincinnati Hospital is open to the students for study. Board can be procured in Cincinnati for from $3 to $5 per week. The Laura Memorial Woman's Medical College has ceased to exist.

Cleveland, population 381,768, contains three medical schools: Western Reserve University Medical College, Cleveland College of Physicians and Surgeons and the Cleveland Homeopathic Medical College. The City Hospital, with 275 beds, is used in common by them for clinical study. Board and lodging can be had for from $2.50 to $5 a week.

Columbus, population 125,560, contains two: Starling Medical College and Ohio Medical University. Board and lodging cost from $2.50 to $5 per week.

Toledo, with 131,822 people, has one medical school: Toledo Medical College. It has good clinical advantages. Board and room can be had for from $3 to $5 a week.

Cincinnati.

Medical College of Ohio.—This is the Medical Department of the [illegible] ized in 1819, and has a faculty made [illegible] ers and assistants, a total of 56. Good [illegible] 100 beds; Cincinnati Hospital, with [illegible] college dispensary furnish clinical [illegible]. The buildings supply ample laboratory and lecture-room space, and their equipment is good. The course of study is graded and covers four years of eight months each. This school is a member of the Association of American Medical Colleges. The lecture fees are $125 each year for each student entering after July 1, 1903; $100 each year for those who have matriculated prior to July 1, 1903. In addition there is a matriculation fee of $5, payable but once, and a graduation fee of $25. Total registration of students for 1904-5 was 121; graduates, 33. The Dean is Dr. P. S. Conner, Cincinnati. The next session begins Sept. 28, 1905, and ends May 30, 1906.

Miami Medical College.—This school was organized in 1852, and has a faculty of 23 professors and 35 lecturers and demonstrators, a total of 58. The clinical facilities are furnished by the Cincinnati Hospital and a college dispensary. This college is a member of the Association of American Medical Colleges. The curriculum embraces a four-year graded course of eight months each. The total fees are, for the first year, $130; for the second and third, $125, and $150 for the fourth year. The Dean is Dr. J. C. Oliver, 628 Elm St. The total registration for 1904-5 was 85; graduates, 24. The next session opens Oct. 1, 1905, and closes June 1, 1906.

Eclectic Medical Institute.—This school, organized in 1845, has a faculty of 21 members. The Seton Hospital, Cincinnati Hospital, and a college dispensary furnish clinical material. It is a member of the National Confederation of Eclectic Medical Colleges. The course covers four years of thirty weeks each. The fees are $75 for each year, with a graduation fee of $25. The Dean is Dr. Rolla L. Thomas, 792 East McMillan St. Total enrolment, 1904-5, was 135; graduates, 18. The next session begins Sept. 18, 1905, and closes April 18, 1906.

Pulte Medical College.—Homeopathic. This was organized in 1872 and has a teaching force of 21 professors and 17 assistants, 38 in all. Pulte Hospital, Cincinnati Hospital, Bethesda Hospital, Home of the Friendless and Foundlings, and a college dispensary supply clinical material. The curriculum covers four years of seven months each. Fees: First year, $80; for the second and third, $75 each, and $100 for the fourth. The Dean is Dr. Charles E. Walton. Total enrolment for 1904-5 was 18; graduates, 5. The next session opens Sept. 27, 1905, and closes May 1, 1906.

Cleveland.

The Cleveland College of Physicians and Surgeons.—This school was organized in 1863 as Charity Hospital Medical College, became the Medical Department of Wooster University in 1869, and the Medical Department of the Ohio Wesleyan University in 1896, when it assumed its present title. The faculty is composed of 28 professors, 8 assistant professors, 29 lecturers, assistants, instructors, etc, 59 in all. Cleveland General Hospital, Cleveland City Hospital and a college dispensary are used for regular clinical teaching. St. Alexis, St. John's, St. Clair and Mt. Sinai hospitals are utilized for extra-mural clinics. This school is a member of the Association of American Medical Colleges. The school is co-educational. The total annual fees are $130. The curriculum covers four years of eight months each. The Dean is Dr. R. E. Skeel, 785 Prospect St. Total enrolment for 1904-5 was 84; graduates, 16. The next term opens Sept. 20, 1905, and closes May 4, 1906.

Western Reserve University Medical College.—The Medical Department was organized in 1843. Its teaching faculty includes 23 professors, 31 lecturers, demonstrators and assistants, a total of 54. Clinical facilities are offered students of this school by Lakeside Hospital, having 250 beds; St. Vincent's Hospital, having about 150 beds; City Hospital, with 250 beds; St. Alexis Hospital, with 250 beds, and the Home of Maternity, with the dispensary service at Lakeside and Charity hospitals, and a tuberculous dispensary at the college. The laboratory chairs are endowed, the teachers devoting their entire time to teaching and research work. A clinical laboratory has recently been added, where a systematic course of instruction is given. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight months each. Three years of college work are required for admission to first year of medical course. The total fees are $125 for each year. The Dean is Dr. B. L. Millikin, 260 Euclid Avenue. Total enrolment for 1904-5 was 73; graduates, 6. The next session begins Oct. 1, 1905, and closes June 4, 1906.

Cleveland Homeopathic Medical College.—This school was founded in 1897 by a consolidation of Cleveland University of Medicine and Cleveland Medical College, the former of which was incorporated in 1850, and is the second oldest homeopathic medical college in the United States. The faculty includes 34 professors and 29 adjuncts, lecturers, etc., 63 in all. The clinical facilities are obtained from the Cleveland Homeopathic Hospital, the Cleveland City Hospital, the Cleveland Maternity Hospital, and a college dispensary. The course embraces four years of thirty weeks each. Fees: First year, $110; second and third years, $105 each, and $125 for the fourth year. The Dean is Dr. Gaius J. Jones. Total number of students registered, 1904-5 was 66; graduates, 24. The next session opens Sept. 27, 1905, and closes May 16, 1906.

Columbus.

Ohio Medical University.—This school was organized in 1890, and has a faculty of 22 professors, 6 instructors, 5 assistants and 2 demonstrators, 35 in all. The protestant Hospital, State Hospital, Ohio Penitentiary Hospital and a college dispensary provide material for clinical work. This school is a member of the Association of American Medical Colleges. The course is four years of 34 weeks each. Fees: First year, $105; second year, $100; third year, $100, and $110 for the fourth year. The Dean is Dr. George M. Waters. Total students for 1904-5 was 158; graduates, 37. The next session begins Sept. 12, 1905, and ends May 8, 1906.

Starling Medical College.—This school was organized in 1847 and has a faculty composed of 20 professors and 16 lecturers, associates, etc., a total of 36. St. Francis Hospital, which is under the control of this faculty; Hawkes' Hospital of Mt. Carmel, the Lawrence Hospital, St. Anthony Hospital and a college dispensary are available for clinical study. This college is a member of the Association of American Medical Colleges. The work covers four years of thirty weeks each. Fees: $100 per year; matriculation fee, $5; graduation fee, $10. The Dean is Dr. Starling Loving. Enrolment for 1904-5 was 105; graduates, 30. The next session opens Sept. 13, 1905, and closes May 5, 1906.

Toledo.

Toledo Medical College.—The school was organized in 1882, and in 1904 became the Medical Department of Toledo University. It has a faculty of 20 professors, 20 lect[illegible] all 40. Toledo Hospital, St. Vincent's ar[illegible] Lucas County Infirmary Hospital, Toledo [illegible] and a free dispensary supply clinical facilities. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight months each. The fees are $75 for each year, with a matriculation fee of $5, payable once. The Dean is Dr. W. A. Dickey, 10 Hartford Block. Total enrolment for 1904-5 was 83; graduates 7. The next session opens Sept. 22, 1905, and closes May 11, 1906.

OKLAHOMA.

Oklahoma, population 398,331, has only one medical school, which is located at Norman, a city of about 3,682 inhabitants.

Norman.

School of Medicine, University of Oklahoma.—This school, which was organized in 1903, teaches only the first two years of the regular medical course, each course extending over a period of nine months. Total registration for 1904-5 was 8. The Dean is Dr. R. P. Stoops; the Registrar, Roy Hadsell. The next session begins Sept. 12, 1905, and ends June 9, 1906.

Oklahoma City.

College of Medicine Epworth University.—In 1904 only the first year of the medical course was given, but beginning October, 1905, the full four years' course will be taught. The faculty consists of 15 professors and 12 assistants, instructors, etc., a total of 27. The Oklahoma City, St. Anthony's hospitals, Amie Rescue Home and a college dispensary furnish material for clinical instruction. The laboratories are well supplied and the lecture rooms are large, well lighted and well ventilated. The entrance requirement is a high school diploma or its equivalent. The course of study embraces graded work for four years of seven months each. The total fees are about $70 each year. The Dean is Dr. A. K. West; Secretary, Dr. H. C. Todd. The registration for 1904-5 was 7; no graduates. The next session begins Oct. 3, 1905, and ends May 11, 1906.

OREGON.

Oregon, population 413,536, has two medical colleges: Medical Department Willamette University, located in Salem, a city of 10,000 people, and University of Oregon Medical Department, in Portland, a city of about 125,000 population. Board and lodging may be obtained in Salem for from $3 to $5 per week, and in Portland for from $4 to $6.

Salem.

Medical Department Willamette University.—The school was organized in 1864. The faculty consists of 19 teachers. Clinical facilities for study are supplied by Salem Hospital, and a college dispensary. This school is a member of the Association of American Medical Colleges. The course embraces four years' work of six months each. Fees: First year, $110; second, $100; third, $75, and $50 for the fourth year. The Dean is Dr. W. H. Byrd. Total enrolment for 1904-5 was 50; graduates, 7. The next session begins Oct. 1, 1905, and ends March 30, 1906.

Portland.

University of Oregon Medical Department.—This department of the State University was organized in 1887, and has a faculty of 14 professors and 14 assistants, lecturers, etc., a total of 28. Good Samaritan and St. Vincent's hospitals, containing 200 and 350 beds, respectively, and Multomah County Hospital furnish good material for clinical study. The requirements for admission are those of the Association of American Medical Colleges, but the members of the faculty do not hold examinations for entrance. *The college building is modern and well equipped, presenting ample teaching facilities.* The course is four years of seven months each. Fees: First year, $142.50; second, $137.50; third, $107.50, and for the fourth, $57.50. The Dean is Dr. Simeon E. Josephi, Portland. The total number of students for 1904-5 was 102; graduates, 26. The next session opens Sept. 15, 1905, and closes April 30, 1906.

PENNSYLVANIA.

Pennsylvania, population 6,302,115, has seven medical colleges. Of these Philadelphia, having a population of 1,293,697, contains six as follows: University of Pennsylvania Department of Medicine, Jefferson Medical College, Hahnemann Medical College, Woman's Medical College of Pennsylvania, Medico-Chirurgical College of Philadelphia and Temple College Department of Medicine. The clinical facilities of Philadelphia present abundant and varied material for study. Beside the individual hospitals connected with each of the schools the charity hospitals are open to all the students in common. *Board and lodging costs from $4 a week upward.*

The other school, Western Pennsylvania Medical College, is situated in Pittsburg, a city of 321,616 people. The cost of board and lodging is from $4 to $6 a week.

Philadelphia.

University of Pennsylvania Department of Medicine.—This is the first medical college established in this country, having been organized in 1765 as the Medical Department of the College of Philadelphia; the first degree was granted in 1768. When from the College of Philadelphia the University of Pennsyylvania was organized, in 1791, it became the Medical Department of the University, its present relation. The faculty is made up of 27 professors, 2 associate professors, 4 adjunct professors, 7 assistant professors, 97 demonstrators, lecturers, assoociates, instructors, etc., a total of 137. Abundant and varied clinical material is furnished by the University Hospital, capacity 300 beds, which treats over 14,000 [illegible] Maternity Pavillion, with 50 beds; [illegible] aining 1,000 beds; Pennsylvania, Child[illegible] Hospital and Dispensary. Special attention is paid to bedside instruction and to thoroughly practical work. Applicants for admission must furnish evidence of the education required to enter the academic department of the university. The buildings known as Medical Hall, Medical Laboratory Building, the laboratories of Pathology, Physiology and Pharmacology, the Laboratory of Hygiene, the Wistar Institute of Anatomy, and the Wm. Pepper Clinical Laboratory supply excellent laboratory and lecture-room facilities and are well equipped. The course embraces study for four years of nine months each. The total fees for each year are $200, with a matriculation fee of $5 for the first year. The Dean is Dr. Charles H. Frazier. Total enrolment for 1904-5 was 546; graduates, 116. The next session opens Sept. 29, 1905, and closes June 20, 1906.

Jefferson Medical College of Philadelphia.—This school was organized in 1825, and has a faculty of 29 professors and 81 lecturers, demonstrators, etc., a total of 110. Jefferson Hospital, together with its maternity Department, are used exclusively by students of the school for clinical study. *Bedside instruction is given* daily to small sections of the senior class. In addition, the following hospitals are open for study of clinical cases: Pennsylvania, Philadelphia, St. Joseph's, German, Municipal and Wills Eye hospitals. The course of study covers graded work of four years of eight months each. The laboratories are large and well equipped, a new five-story laboratory building having recently been added: the lecture rooms and amphitheaters are also ample. A new fireproof hospital is now building, to cost $1,000,000, to be finished in 1906. The tuition is $180 a year, with a matriculation fee of $5, paid but once. The Dean is Dr. James W. Holland. The total number of students for 1904-5 was 676; graduates, 179. The next session opens Sept. 25, 1905, and closes June 4, 1906.

Medico-Chirurgical College of Philadelphia.—This school was organized in 1881, and has a faculty made up of 25 professors and 55 assistants, lecturers, etc, 80 in all. Opportunities for clinical study are offered exclusively to students of this school by the Medico-Chirurgical Hospital, with 125 beds, and its children's and maternity hospital, having 30 beds. In common with other schools, the following are used: Philadelphia, Pennsylvania, German, Samaritan, St. Joseph's, St. Agnes', St. Mary's, Methodist, Jewish and the Philadelphia Lying-in hospitals. This school is a member of the Association of American Medical Colleges. With new laboratories, lecture rooms, a modern hospital and fine clinical amphitheater, this college is amply provided and the equipment is good. The work embraces four years of eight months each. Fees: $150 per annum; matriculation, $5, payable once. The Dean is Dr. Seneca Egbert. Total enrolment, 1904-5 was 461; graduates, 86. The next session opens Sept. 25, 1905, and will close June 2, 1906.

Woman's Medical College of Philadelphia.—This school was organized in 1850, and has a faculty of 10 professors and 38 assistants, lecturers, etc., in all 48. Clinical facilities are offered by the Hospital of the Woman's Medical College of Pennsylvania, Woman's Hospital, West Philadelphia Hospital for Women, German, Jewish, Children's and Philadelphia hospitals, Presbyterian hospital, Wills Hospital for Diseases of the Eye, the Howard Hospital and the Philadelphia Lying-in Charity. This school is a member of the Association of Ameriacn Medical Colleges. The lecture room and laboratory equipment is good. The curriculum covers four years of eight months each. Fees: First year, $140; second, $145; third, $135.50, and $100.50 for the fourth year. The Dean is Dr. Clara Marshall. Total enrolment for 1904-5 was 151; graduates, 42. The next session begins Sept. 27, 1905, and will end may 23, 1906.

Hahnemann Medical College and Hospital.—Homeopathic. This was organized in 1848, and has a fa[illegible] and 56 lecturers, instructors, etc., in all 73. [illegible] Hospital and Pennsylvania Hospital furnish [illegible] work. The requirements for admission are those established by the Intercollegiate Committee of the American Institute of Homeopathy. The work covers four years of thirty-two weeks each. Fees: For each year, $150; matriculation, $5. Total number of students for 1904-5 was 164; graduates, 44. The Dean is Dr. Charles M. Thomas. The next session begins Sept. 25, 1905, and will end May 24, 1906.

Medical Department of the Temple College.—This department was organized in 1901, and has a faculty of 18 professors and 22 assistants, etc., a total of 40. Instruction is given in the afternoon and evening, and the course extends over five years of nine months each. The fees are $125 per year. The Dean is Dr. I. Newton Snively. The enrolment for 1904-5 was 87; graduates, 2. School opens Sept. 18, 1905, and closes June 15, 1906.

Pittsburg.

Western Pennsylvania Medical College.—This is the Medical Department of the Weste[illegible]nsylvania, and was organized in 1886. The [illegible] 38 professors and 54 associates, assistants, e[illegible] material for study [illegible] college dispensary, and the Emma Kaufman [illegible]aternity Hospital, Mercy, South Side, Passa[illegible] hospitals. This school is a member of the Association of American Medical Colleges. The course of study embraces graded work for four years of nine months each. Special attention is given to practical bedside work. The total fees are $150 for each year. The Dean is Dr. J. C. Lange. Total enrolment for 1904-5 was 281; graduates, 53. The next session begins Oct. 1, 1905, and will close June 1, 1906.

PHILIPPINE ISLANDS.

Manila.

University of Saint Thomas Medical Department.—The University was founded by a papal decree in 1587, and the medical school was added in 1871. The faculty consists of 81 teachers. The course extends over a period of six years of nine months each. The first year is a preparatory one, devoted to the teaching of physics, chemistry and biology. The degree of licenciado is conferred at the conclusion of the fifth year, and the degree of doctorado at the end of the sixth year, during which only special work is done. This last year is optional, the degree of licenciado entitling the holder to all the rights and privileges of the medical practitioner. The degree is equivalent to the English M.B. The Rector of the University is Dr. Fr. Raymundo Velasquez; the Secretary of the medical department is Lic. Blas C. Alcuaz. Total registration for 1903-4 was 68; graduates, 14. The course began July 2, 1904, and ended March 7, 1905.

SOUTH CAROLINA.

South Carolina, population 1,340,316, has one medical college, situated in Charleston, a city of 55,807 people. Board and room can be obtained for from $12 to $16 a month.

Charleston.

The Medical College of the State of South Carolina.—This school was founded in 1823. The faculty is made up of 10 professors and 10 assistants, etc., 20 in all. The clinical facilities are those offered by the City Hospital, where surgical, obstetrical and medical instruction is given. Applicants for matriculation must show a diploma of graduation from some literary or scientific institution of learning or a certificate from some legally constituted high school. The course covers four years of six months each. The total fees for each of the first two years are $100, and $75 each for the last two. The Dean is Dr. Francis L. Parker. Total enrolment for 1904-5 was 87; graduates, 28. The next session opens Oct. 1, 1905, and closes April 15, 1906.

TENNESSEE.

Tennessee, population 2,020,616, has ten medical colleges. Of these the Medical Department of the University of Nashville, Vanderbilt University Medical Department, University of Tennessee Medical Department, and Meharry Medical College are situated in Nashville, a city with a population of 80,865. The City Hospital, containing 100 beds, is used by all the schools in common for clinical study. Board and lodging cost from $3 to $4 a week.

Knoxville, population 32,637, contains two colleges, Tennessee Medical College and Knoxville Medical College. The cost of room and board in that city is from $2.50 to $4 a week.

Chattanooga Medical College and Chattanooga National Medical College are situated in Chattanooga, a city of 30,154 people. Board and lodging cost there from $2 a week upward.

Memphis Hospital Medical College is located in the growing city of Memphis, population 102,320. Good board can be obtained for from $3 to $4 a week.

The University of West Tennessee is in Jackson, whose population is 15,000.

The other school, the Sewanee Medical College, is located at Sewanee, a mountain town of 1,200 people.

Nashville.

University of Nashville Medical Department.—This school, established in 1850, has a faculty of 12 professors and 11 lecturers, assistants, etc., in all 23. This school is a member of the Southern Medical College Association. The course of study covers four years of twenty-six weeks each. The tuition for each of the four years is $65. The Dean is Dr. William G. Ewing. Total enrolment for 1904-5 was 317; graduates, 75. The next session begins Oct. 2, 1905, and ends March 30, 1906.

Vanderbilt University Medical Department.—This school was founded in 1874, and in 1895, when the present medical building was completed, the course was extended, the standard raised. The present faculty of 35 consists of 20 professors and 15 lecturers, etc. The school is a member of the Southern Medical College Association. The course covers four years of seven months each. The minimum entrance requirement is a high school diploma or its equivalent. The total fees for the first three years are $105 each, and $130 for the fourth year. The Dean is Dr. William L. Dudley. Total enrolment for 1904-5 was 159; graduates, 35. The next session begins on or about October, 1905, and ends in April, 1906.

University of Tennessee Medical Department.—This was organized in 1876 as the Nashville Medical College; its present relations were assumed in 1879. The faculty is composed of 20 professors and 5 lecturers, assistants, etc., 25 in all. The school is a member of the Southern Medical College Association. The course of study includes work for four years of six months each. The total fees for each of the first three years are $65 and $90 for the fourth year. The Dean is Dr. Paul F. Eve, 614 Broad St. Total enrolment for 1903-4 was 164 students; graduates, 33. The next session begins Oct. 2, 1905, and ends April 2, 1906.

Meharry Medical College.—Colored. This school was organized in 1876 as the Medical Department of Central Tennessee College, now Walden University, "for the purpose of furnishing to the colored people of the South an opportunity of obtaining a medical education." The faculty is made up of 10 professors and 12 instructors, demonstrators, etc., 22 in all. The work embraces a four-year graded course, seven months to the year. The total fees for the first three years are $40 each, and $50 for the fourth year. The Dean is Dr. G. W. Hubbard. Total registration for 1904-5 was 328; graduates, 59. The next session begins Sept. 1, 1905.

Knoxville.

Tennessee Medical College.—This school was organized in 1889, and has a faculty of 14 professors and 12 assistants, 26 in all. A new building with large and well-fitted laboratories has been completed. City General Hospital and a fee dispensary supply material for study of clinical cases. This school is a member of the Southern Medical College Association. The curriculum includes graded work for four years of seven months each. Fees: Matriculation, $5; annual fee, $50; graduation fee, $25. The Secretary is Dr. S. L. Jones. Total number of students for 1904-5 was 92; *graduates*, 13. The next annual session begins Nov. 1, 1905, and closes June 1, 1906.

Knoxville Medical College.—Colored. This school was established in 1900, following the discontinuance of the Medical Department of Knoxville College, organized in 1895. The teaching force comprises 12. The course covers four years of seven months each. Fees: $40 per year. The Secretary is Dr. H. M. Green. Total number of students for 1904-5 was 47; *graduates*, 6. The next session opens Nov. 10, 1905, and closes June 1, 1906.

Chattanooga.

Chattanooga Medical College.—This is the Medical Department of Grant University, and was organized in 1889. The faculty consists of [illegible] instructors, demonstrators, etc., total 26. [illegible] ilities are afforded by the wards of Barone [illegible] a county asylum, an outdoor clinic main [illegible] building, and all material furnished by the [illegible] which the faculty desire to utilize. The scholastic requirements are those of the Southern Medical College Association, of which this school was a charter member, and to which it belongs. These requirements involve a strictly graded course covering four years of six months each. The total fees approximate $55 each session. The trustees materially added to the general facilities of the institution by the erection of another fine four-story building of brick and stone for the medical department three years ago, wherein much modern and elaborate equipment has been installed. The Dean is Dr. E. A. Cobleigh. The total enrolment for the session of 1904-5 was 268; graduates, 39. The next session opens about Oct. 1, 1905, and ends about April 7, 1906.

Memphis.

Memphis Hospital Medical College.—This school, organized in 1878, has a faculty of 10 professors and 18 assistants, beside quiz masters. Excellent clinical facilities are furnished by the City Hospital, Presbyterian Hospital, St. Joseph's Hospital and the East End Dispensary, the latter being located in the college building. The course includes graded work for four years of six months each. The total fees for the first three years are $65; for the fourth, $90. The Dean is Dr. W. B. Rogers. Total registration for 1904-5 was 476; graduates, 151. The twenty-sixth annual session will begin Oct. 1, 1905, and close April 30, 1906.

Jackson.

Medical Department of the University of West Tennessee.—Colored. This school, organized in 1900, has a faculty of 12. The course is four years of seven months each. The fees are $40 per year; graduation, $10 extra. Registration for 1904-5 was 33; graduates, 6. The next session opens Sept. 18, 1905, and closes April 18, 1906.

Sewanee.

Medical Department of the University of the South (Sewanee Medical College).—This school was organized in 1891, and has a faculty of 23. It is a member of the Southern Medical College Association. The course is four years of seven months each. The fees are $65 for each of the first two years, $55 for the third and $80 for the last year. The Dean is Dr. John S. Cain. Total enrolment for 1904-5 was 132: graduates, 36. The fourteenth session commences April 1, 1905, and will close October 25, 1905.

TEXAS.

Texas, population 3,048,710, has seven medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 37,789 inhabitants. Good board and room can be procured for from $15 to $20 a month.

The Medical Department of Fort Worth University is at Fort Worth, population 35,000. The cost of board and room in that city is from $12 to $15 a month.

The Baylor University College of Medicine, the Medical Department of Southwestern University, the College of Physicians and Surgeons, and the Physio-Medical College of Texas are situated in Dallas, population 55,000.

The Gate City Medical College is situated in Texarkana.

Dallas.

Baylor University College of Medicine.—This is a new name for the University of Dallas Medical Department, which was organized in 1901. In June, 1903, it became the Medical Department of Baylor University at Waco. The faculty numbers 20 professors and 16 assistants, total 36. Parland Hospital, with 90 beds; St. Paul's Sanitarium, Baptist Memorial Hospital and a college dispensary and hospital are utilized for clinical study. The course covers four years of seven months each. The school is a member of the Association of Southern Medical Colleges. The fees are $75 *for each of the four years*, with a matriculation fee of $5 paid once, and a graduation fee of $25. The Dean is Dr. E. H. Cary. Total registration for 1904-5 was 132; graduates, 36. The next session opens Oct. 2, 1905, and closes May 1, 1906.

Galveston.

University of Texas Medical Department.—This department of the State University was organized in 1891, and has a faculty of 27. The John Sealy Hospital, also having an outdoor department, and St. Mary's Infirmary supply good material for clinical study. The requirements for admission are proof, either by certificate or examination, that the candidate is sufficiently proficient in English, including grammar, composition and rhetoric; mathematics through plane geometery and algebra, including quadratics, and general history. The curriculum embraces graded work for four years of eight months each. [illegible] stry, physiology, pharmacology, anatomy, [illegible] histology, pharmacy and clinical medicine [illegible] for practical work by students. Fees, to re [illegible] irst year, $50; second and third, each $20, [illegible] for the fourth. Non-residents of the state are required to pay an additional fee of $50 each year. The President is Dr. William L. Prather; the Dean is Dr. William S. Carter. Total registration for 1904-5 was 169; graduates, 23. The next session begins Oct. 7, 1905, and ends May 31, 1906.

Ft. Worth.

Medical Department of Fort Worth University.—This school was organized in 1894, and has a faculty of 15 professors and 17 lecturers, assistants, etc., in all 32. Clinical facilities are supplied by St. Joseph's Hospital, with 200 beds; the Benevolent Home, containing 75 beds; the Gelia Collins' Rescue Home, having 50 beds, and a college dispensary. The school is a member of the Southern Medical College *Association*. The course covers four years of six months each. The total fees for each of the first three years are $75 and $100 for the fourth year. The Dean is Dr. Frank Gray. The total enrolment for 1904-5 was 191; graduates, 21. The next session opens Oct. 2, 1905, and closes April 6, 1906.

Southwestern University Medical College.—This is the Medical Department of Southwestern University and was organized in June, 1903. It has a faculty of 18 professors and 19 instructors, total 37. The course of instruction is graded and covers four years in medicine and two in pharmacy. Requirements for admission are equivalent to those prescribed by the Association of American Medical Colleges. The fees are: Matriculation, $5, paid once; annual tuition, $75; graduation, $25. The hospitals represented by the faculty and open for clinical teaching are: St. Paul's Sanitarium, Cit[illegible] Home, Rescue Home, Woman's Home, St. [illegible] Matthew's Home for Children, Dr. H. K. L[illegible], Out Door Clinic of the Settlement Home and Presbyterian Home for Children. The Dean is Dr. John O. McReynolds. Total registration 1904-5 was 65; graduates, 14. The third session opens Oct. 2, 1905, and closes May 3, 1906.

College of Physicians and Surgeons.—This school was founded in 1904, and in 1905 the name was changed to College of Physicians and Surgeons. It has a total teaching staff of 15. The course of instruction extends over four years of six months each. The requirements for admission are the same as those prescribed by the Association of Southern Medical Colleges. Clinical instruction is given in the City Hospital, St. Paul Sanitarium and the college dispensary. The fees for the first three years are $80, and $105 for the fourth year. The Dean is Dr. A. C. Bell. Total registration for 1904-5 was 108; graduates, 17. The next session begins Oct. 3, 1905, and closes April 3, 1906.

Physio Medical College of Texas.—This college was organized in 1902. It has a faculty of 24 professors and 4 assistants, total 28. The course is four years of thirty weeks each. The fees are, first year, $70; fourth year, $85; other years, $65. Enrolment 1904-5 was 42; graduates, 5. The Secretary is Dr. R. L. Spann. The next session opens Oct. 15, 1905, and closes May 15, 1906.

Texarkana.

Gate City Medical College.—The length of each course is seven months. The faculty numbers 20 professors and assistants. Registration 1904-5 was 109; graduates, 26. The Dean is Dr. J. W. Decker. The next session begins Oct. 26, 1905, and ends May 4, 1906.

VERMONT.

Vermont, population 343,641, has one medical school, located at Burlington, a town of about 20,000 people. Board and room costs from $3.50 to $5 a week.

Burlington.

University of Vermont College of Medicine.—This school was organized in 1822, but suspended from 1836 until 1854, when it was reorganized. The faculty consists of 20 professors and 21 assistants, instructors, etc., in all 41. The Mary Fletcher Hospital and a free dispensary furnish material for clinical instruction. Applicants for admission must be graduates of a four-year high school course or take an examination to show equivalent educational qualifications. The laboratory and lecture-room space and equipment are good. A new and commodious college building is nearly completed. The course of study embraces graded work for four years of seven months each. The total fees for each of the first three years are $115 and $140 for the fourth year. The Dean is Dr. H. C. Tinkham; Secretary, H. L. White, A.M. Total registration of students for 1904-5 was 185; graduates, 48. The fifty-third session begins Dec. 2, 1905, and ends June 27, 1906.

VIRGINIA.

Virginia, population 1,854,184, has three medical colleges, situated in Charlottesville (population 6,449) and Richmond (population 85,050). The clinical facilities in Richmond are good. Board and room can be obtained for $18 a month, and upward, in Charlottesville, and from $12 to $20 a month in Richmond.

Charlottesville.

University of Virginia Department of Medicine.—This school was organized in 1827, and has a faculty of 24. A free dispensary and the new four-story hospital furnish clinical facilities. The requirements for admission are those of the Association of American Medical Colleges. The course is four years of nine months each. Fees: First year, $110; second, $100; third, $80, and $60 for the fourth year. Total enrolment for 1904-5 was 145; graduates, 38. The eighty-first session opens Sept. 14, 1905, and closes June 13, 1906.

Richmond.

Medical College of Virginia.—This school was organized in 1838 as the Medical Department of Hampden Sidney College, Virginia. In 1854 it was granted a charter by the Legislature of Virginia as an independent institution under its present name. In 1860 the college and its appurtenances was deeded to the State of Virginia in consideration of an appropriation on the part of the state of a sufficient sum to build a hospital, since which time it has continued as a state institution. During the war between the states it was the only medical college in the Confederacy which did not close its doors. It held two sessions a year during this period, and a large proportion of the surgeons of the Confederate Army were graduates of this school. Clinical material was formerly furnished by the Old Dominion Hospital, but more recently by the Memorial Hospital, opened in July, 1903, and the City Free Dispensary, both of which are under the exclusive control of this college. An outside obstetric service, the State Penitentiary Hospital, the City Almshouse Hospital and other public charities and asylums of the city afford ample opportunity for additional clinical work. This school is a member of the Southern Medical College Association. The buildings are large and numerous and contain well-equipped laboratories and amphitheaters. The course embraces four years of nearly eight months each. The fees are $85 for each year, with an additional graduation fee of $30. The Dean is Dr. Christopher Tompkins. Total registration for 1904-5 was 209; graduates, 38. The next session begins Sept. 24, 1905, and will end May 16, 1906.

University College of Medicine.—This school was organized in 1893, and has a faculty of 19 professors, 41 lecturers, assistants, etc., a total of 60. Good clinical facilities are furnished by Virginia Hospital, with a maternity [illegible] h was built especially for the purpose o[illegible] n, and is owned and operated by the [illegible] r and Throat Infirmary, containing 34 [illegible] y Jail, State Penitentiary, and a colleg[illegible] is in accord with the rules of the Association of American Medical Colleges, and of the Southern Medical College Association, to both of which this college belongs. The laboratory and lecture-room space and equipment are ample, and some of the instructors devote their entire time to the laboratories. The school lays especial importance on the careful instruction and guidance of each student. The curriculum covers four years of thirty-four weeks each. The total fees are $85 for each year. The President is Dr. Stuart McGuire; the Dean is Dr. Landon B. Edwards, Richmond. Total enrolment for 1904-5 was 223; graduates, 48. The next session begins Sept. 26, 1905, and ends May 24, 1906.

WEST VIRGINIA.

West Virginia, population 958,800, has one medical college, College of Medicine of the West Virginia University, located at Morgantown, a city of 10,000 inhabitants.

Morgantown.

West Virginia University College of Medicine.—This school was organized in 1903, and gives only the first two years of the medical course. Each college term extends over nine months. The degree of M.D. is granted students after they finish the third and fourth years in Baltimore at the College of Physicians and Surgeons. The faculty consists of 5 professors and 4 assistants, 9 in all. The school is a member of the Association of American Medical Colleges. Dr. J. N. Simpson is the Dean and A. J. Collett the Secretary. Total registration in 1904-5 was 36. Next session begins Sept. 21, 1905, and closes June 15, 1906.

WISCONSIN.

Wisconsin, poplation 2,069,042, has two medical colleges, the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons. They are both situated in Milwaukee, a city of 300,000 people. Clinical facilities are furnished them in common by the County Hospital, with 300 beds, and the Milwaukee Hospital for the Insane. Board and lodging can be had for from $3 to $5 a week.

Milwaukee.

Milwaukee Medical College.—This school was organized in 1893, and has a faculty of 36 professors and 27 lecturers, instructors, etc., a total of 63. Good clinical material is furnished by Trinity and the County hospitals, Milwaukee Hospital for the Insane, and a [illegible] This school is a member of the Association of [illegible] lleges. Ample laboratory and amphitheater [illegible] The course covers four years of eight mont[illegible] s are $125 each for the first three years and $135 for the fourth year. The President is Dr. William H. Earles. Total number of students for 1904-5 was 174; graduates, 38. The twelfth session begins Oct. 2, 1905, and will close about June 4, 1906.

Wisconsin College of Physicians and Surgeons.—This college was organized in 1893, and has a faculty composed of 21 professors and 25 associates, assistants, etc., a total of 46. St. Joseph's Hospital, containing 150 beds; the college dispensary, the Milwaukee County Hospital and the Hospital for the Insane supply facilities for clinical study. The school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are well equipped. The curriculum includes four years of eight months each. Fees: Matriculation, paid once, $5; general ticket, $100; for the use of the microscope, a fee of $2 is charged for each course. The Secretary is Dr. W. H. Washburn. Total enrolment for 1904-5 was 74; graduates, 19. The next session begins Sept. 19, 1905, and ends May 16, 1906.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

The requirements for admission and graduation to be maintained by colleges holding membership in this association and the minimum course of study prescribed, are as follows:

ARTICLE III.

Section 1.—Every college holding membership in this Association shall demand of each student, under the condition hereinafter stated, as a minimum requirement for admission to the medical course:

(*a*) A bachelor's degree from an approved college or university.

(*b*) A diploma from an accredited high school, normal school or academy requiring for admission evidence of the completion of an eight-year course in primary and intermediate grades, and for graduation not less than four years of study embracing not less than two years (4 points) of foreign language, of which one must be Latin, two years (4 points) of mathematics, two years (4 points) of English, one year (2 points) of history, two years (4 points) of laboratory science, and six years (12 points) of further credit in language, literature, history or science.

(*c*) An examination in the following branches:

A. Required (18 points): Mathematics (4 points); English (4 points); History (2 points); Language (2 must be Latin), 4 points; Science (taken from physics, chemistry, botany, zoology), 4 points.

B. Optional (to 12 points): English, 2 points, History, 6 points; Language, 6 points: Manual Training, 2 points; Mechanical Drawing, 1 point; Natural Science (botany, biology, zoology), 2 points; Physical Science (chemistry, physics), 2 points; Trigonometery, 1 point; Astronomy (1), Civics (1), Geology (1), Physical Geography (1), Physiology and Hygiene (1), Political Economy (1).

(One point in any subject in a high school or academic course demands not less than five periods per week of forty-five minutes each for eighteen weeks).

(*d*) Certificates from reputable instructors recognized by the superintendent hereinafter to be mentioned or by any state board of medical examiners duly authorized by law, may be accepted in lieu of any part of this examination.

Sec 2.—This examination must be conducted by or under the authority of the superintendent of public instruction of the city or state in which the college is located. In no case shall it be conducted by any person connected with the faculty, medical or otherwise, of the institution to which the student is seeking admission.

Sec. 3.—A student may be allowed to enter on his medical work conditioned in not more than six points, and these conditions must be removed by satisfactory examination before he is allowed to enter on the second year of his medical course.

Sec. 4.—Colleges in membership in this Association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of their course, but no member of this Association shall admit a student to advanced standing without first communicating with the college from which such student desires to withd[illegible] the dean of such college a direct written [illegible] to the applicant's professional and mor[illegible] the exact work he has done in said college.

Sec. 5.—Candidates for the degree of Doctor of Medicine shall have attended four courses of study in four calendar years, each annual course to have been of not less than thirty teaching weeks' duration, and at least ten months shall intervene between the beginning of any course and the beginning of the preceding course.

Sec. 6.—Credit may be given to the holder of a Bachelor's Degree from an approved college or university for any work in the medical branches which he has successfully completed in his college course, only so far as it is the full equivalent of corresponding work in the medical curriculum. The holder of such Bachelor's Degree may also be given time credits of not exceeding one year, provided that such student has had at least 40 hours in physics, 144 hours in chemistry, 24 hours in osteology, 292 hours in human or comparative anatomy, 124 hours in histology, 85 hours in embryology, 145 hours in physiology and 46 hours in materia medica; provided that the applicant for such time credits satisfies the professors of the chairs mentioned in the medical school as to his proficiency in these first-year medical studies, and satisfies the examiner, as provided for in Section 2, Article III, that his studies for which the degree was conferred include the above requirements. Such student may be allowed to complete a course for the medical degree in not less than 31 months, provided he completes the remainder of the medical curriculum in that time.

Sec 7.—A college which gives less than a four years' course of study, but does not graduate students, and is possessed of other required qualifications, may be admitted to membership.

Sec. 8.—Each student shall be obliged to attend 80 per cent. of the exercises in every annual course of study for which he seeks credit. No student shall be given credit on examination unless he attains a grade of at least 70 per cent. or its equivalent in any other marking system. And no student shall be graduated unless he shall have attained a passing grade in each and all subjects of the required curriculum.

ARTICLE V.

Section 1.—The entire course of four years shall consist of at least 4,000 hours, divided into the subjects as shown in the following table, and no college shall be recognized that falls below this standard over 20 per cent. in any one branch or over 10 per cent. in the total. Laboratory or clinic hours may be substituted for didactic hours.

Va.; Milwaukee Medical College, Milwaukee, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, Wis.

The secretary-treasurer of the Association is Dr. Fred C. Zapffe, 1764 Lexington St., Chicago.

SOUTHERN MEDICAL COLLEGE ASSOCIATION.

The following requirements for admission to the freshman year are exacted by the colleges belonging to this Association:

Section 3. He must possess a diploma of graduation from some literary or scientific institution of learning, or a certificate that he has passed the entrance examination to a university, or a certificate from some legally constituted high school [general superintendent of state education, or [illegible] e county board of public education, attesting [illegible] larly examined and is possessed of at lea[illegible] ainments required of first-grade teachers of [illegible] ninimum preliminary education required by [illegible] College Association shall be, after Jan. 1, 1906, a grammar school education and two years' successful attendance at a recognized preparatory school or a high school, or its equivalent, said equivalent to be determined by a superintendent of public instruction. A student may be given one month from date of his admission to submit his certificate of qualification. And if he fails to possess the requisite educational qualifications in one or more branches, he may matriculate and attend his first course of lectures, but must present the requisite certificate before matriculating in the second course, and all tickets or certificates issued in such cases must have the conditions printed plainly on the face of each. (After Jan. 1, 1906, that part in brackets becomes non-operative.)

The following colleges are members:

Medical Department University of Tennessee, Nashville, Tenn.; Medical Department University of Nashv[illegible] Medical Department University of the S[illegible] Medical Department Vanderbilt University, [illegible] ical Department Fort Worth University, Fo[illegible] ical College of Virginia, Richmond, Va.; Ten[illegible] Knoxville, Tenn.; Medical College of Alabama, Mobile, Ala; Birmingham Medical College, Birmingham, Ala.; University College of Medicine, Richmond, Va.; Medical Department Baylor University, Dallas, Texas; Medical [illegible] ity of Mississippi, Oxford, Miss.; Memphis [illegible] lege, Memphis, Tenn.; Chattanooga Medical [illegible] Tenn.

The secretary-treasurer is Dr. G. C. Savage, Nashville, Tenn.

AMERICAN INSTITUTE OF HOMEOPATHY.

The minimum requirements for entrance into the freshman class of all homeopathic medical colleges, as adopted in 1901, are, with abbreviation, as follows:

1. English Composition. Exercise on assigned theme, not less than 200 words. Exercise in reading. Exercise in correction of ungrammatical sentences.
2. Mathematics. Arithmetical exercises in (a) vulgar fractions; (b) decimals; (c) percentage; (d) proportion; (e) square and cube root; (f) weights and measures; (g) decimal system. Mensuration. (a) Definition of terms; (b) exercises under the more fundamental rules.
3. Geography (general facts about North America).
4. History. General, with particular reference to human

(Continued on page 570.)

tion is given in the City Hospital, St. Paul Sanitarium and the college dispensary. The fees for the first three years are $80, and $105 for the fourth year. The Dean is Dr. A. C. Bell. Total registration for 1904-5 was 108; graduates, 17. The next session begins Oct. 3, 1905, and closes April 3, 1906.

Physio-Medical College of Texas.—This college was organized in 1902. It has a faculty of 24 professors and 4 assistants, total 28. The course is four years of thirty weeks each. The fees are, first year, $70; fourth year, $85; other years, $65. Enrolment 1904-5 was 42; graduates, 5. The Secretary is Dr. R. L. Spann. The next session opens Oct. 15, 1905, and closes May 15, 1906.

Texarkana.

Gate City Medical College.—The length of each course is seven months. The faculty numbers 20 professors and assistants. Registration 1904-5 was 109; graduates, 26. The Dean is Dr. J. W. Decker. The next session begins Oct. 26, 1905, and ends May 4, 1906.

VERMONT.

Vermont, population 343,641, has one medical school, located at Burlington, a town of about 20,000 people. Board and room costs from $3.50 to $5 a week.

Burlington.

University of Vermont College of Medicine.—This school was organized in 1822, but suspended from 1836 until 1854, when it was reorganized. The faculty consists of 20 professors and 21 assistants, instructors, etc., in all 41. The Mary Fletcher Hospital and a free dispensary furnish material for clinical instruction. Applicants for admission must be graduates of a four-year high school course or take an examination to show equivalent educational qualifications. The laboratory and lecture-room space and equipment are good. A new and commodious college building is nearly completed. The course of study embraces graded work for four years of seven months each. The total fees for each of the first three years are $115 and $140 for the fourth year. The Dean is Dr. H. C. Tinkham; Secretary, H. L. White, A.M. Total registration of students for 1904-5 was 185; graduates, 48. The fifty-third session begins Dec. 2, 1905, and ends June 27, 1906.

VIRGINIA.

Virginia, population 1,854,184, has three medical colleges, *situated in Charlottesville (population 6,449) and* Richmond (population 85,050). The clinical facilities in Richmond are good. Board and room can be obtained for $18 a month, and upward, in Charlottesville, and from $12 to $20 a month in *Richmond.*

Charlottesville.

University of Virginia Department of Medicine.—This school was organized in 1827, and has a faculty of 24. A free dispensary and the new four-story hospital furnish clinical facilities. The requirements for admission are those of the Association of American Medical Colleges. The course is four years of nine months each. Fees: First year, $110; second, $100; third, $80, and $60 for the fourth year. Total enrolment for 1904-5 was 145; graduates, 38. The eighty-first session opens Sept. 14, 1905, and closes June 13, 1906.

Richmond.

Medical College of Virginia.—This school was organized in 1838 as the Medical Department of Hampden Sidney College, Virginia. In 1854 it was granted a charter by the Legislature of *Virginia as an independent institution under its present name.* In 1860 the college and its appurtenances was deeded to the State of Virginia in consideration of an appropriation on the part of the *state of a sufficient* sum to build a hospital, since which time it has continued as a state institution. During the war between the states it was the only medical college in the Confederacy which did not close its doors. It held two sessions a year during this period, and a large proportion of the surgeons of the Confederate Arm [illegible] is school. Clinical material was *formerly* [illegible] Dominion Hospital, but more recently by [illegible] opened in July, 1903, and the City Free Dispensary, both of which are under the exclusive control of this college. An outside obstetric service, the State Penitentiary Hospital, the City Almshouse Hospital and other public charities and asylums of the city afford ample opportunity for additional clinical work. This school is a member of the Southern Medical College Association. The buildings are large and numerous and contain well-equipped laboratories and amphitheaters. The course embraces four years of nearly eight months each. The fees are $85 for each year, with an additional graduation fee of $30. The Dean is Dr. Christopher Tompkins. Total registration for 1904-5 was 209; graduates, 38. The next session begins Sept. 24, 1905, and will end May 16, 1906.

University College of Medicine.—This school was organized in 1893, and has a faculty of 19 professors, 41 lecturers, assistants, etc., a total of 60. Good clinical facilities are furnished by Virginia Hospital, with a maternity department and annex, which was built especially for the purpose of affording bedside instruction, and is owned and operated by the college: Richmond Eye, Ear and Throat Infirmary, containing 34 beds; the City Hospital, City Jail, State Penitentiary, and a college dispensary. Matriculation is in accord with the rules of the Association of American Medical Col*leges, and of* the Southern Medical College Association, to both of which this college belongs. The laboratory and lecture-room space and equipment are ample, and some of the instructors devote their entire time to the laboratories. The school lays especial importance on the careful instruction and guidance of each student. The curriculum covers four years of thirty-four weeks each. The total fees are $85 *for each year. The President* is Dr. Stuart McGuire; the Dean is Dr. Landon B. Edwards, Richmond. Total enrolment for 1904-5 was 223; graduates, 48. The next session begins Sept. 26, 1905, and ends May 24, 1906.

WEST VIRGINIA.

West Virginia, population 958,800, has one medical college, College of Medicine of the West Virginia University, located at Morgantown, a city of 10,000 inhabitants.

Morgantown.

West Virginia University College of Medicine.—This school was organized in 1903, and gives only the first two years of the medical course. Each college term extends over nine months. The degree of M.D. is granted students after they finish the third and fourth years in Baltimore at the College of Physicians and Surgeons. The faculty consists of 5 professors and 4 assistants, 9 in all. The school is a member of the Association of American Medical Colleges. Dr. J. N. Simpson *is the Dean and A. J. Collett* the Secretary. Total registration in 1904-5 was 36. Next session begins Sept. 21, 1905, and closes June 15, 1906.

WISCONSIN.

Wisconsin, poplation 2,069,042, has two medical colleges, the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons. They are both situated in Milwaukee, a city of 300,000 people. Clinical facilities are furnished them in common by the County Hospital, with 300 beds, and the Milwaukee Hospital for the Insane. Board and lodging can be had for from $3 to $5 a week.

Milwaukee.

Milwaukee Medical College.—This school was organized in 1893, and has a faculty of 36 professors and 27 lecturers, instructors, etc., a total of 63. Good clinical material is furnished by Trinity and the County hospitals, Milwaukee Hospital for the Insane, and a college dispensary. This school is a member of the Association of American Medical Colleges. Ample laboratory and amphitheater facilities are afforded. The course covers four years of eight months each. The total fees are $125 each for the first three years and $135 for the fourth year. The President is Dr. William H. Earles. Total number of students for 1904-5 was 174; graduates, 38. The twelfth session begins Oct. 2, 1905, and will close about June 4, 1906.

Wisconsin College *of Physicians* and Surgeons.—This college was organized in 1893, and has a faculty composed of 21 professors and 25 associates, assistants, etc., a total of 46. St. Joseph's Hospital, *containing* 150 beds; the college dispensary, the Milwaukee County Hospital and the Hospital for the Insane supply facilities for clinical study. The school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are well equipped. The curriculum includes four years of eight months each. Fees: [illegible] e, $5; general ticket, $100; for the use of [illegible] $2 is charged for each course. The Secretary [illegible] Total enrolment for 1904-5 was 74; grad [illegible] ession begins Sept. 19, 1905, and ends May 16, 1906.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

The requirements for admission and graduation to be maintained by colleges holding membership in this association and the minimum course of study prescribed, are as follows:

ARTICLE III.

Section 1.—Every college holding membership in this Association shall demand of each student, under the condition hereinafter stated, as a minimum requirement for admission to the medical course:

(*a*) A bachelor's degree from an approved college or university.

(*b*) A *diploma from an accredited high school, normal school* or academy requiring for admission evidence of the completion of an eight-year course in primary and intermediate grades, *and for* graduation not less than four years of study embracing not less *than two years (4 points) of foreign language, of which one must* be Latin, two years (4 points) of mathematics, two years (4 points) *of* English, *one year (2 points) of history, two years (4* points) of laboratory science, and six years (12 points) of further credit in language, literature, history or science.

(*c*) An examination in the following branches:

A. Required (18 points): Mathematics (4 points); English (4 points); History (2 points); Language (2 must be Latin), 4 points; Science (taken from physics, chemistry, botany, zoology), 4 points.

B. Optional (to 12 points): English, 2 points, History, 6 points; Language, 6 points: Manual Training, 2 points; Mechanical Drawing, 1 point; Natural Science (botany, *biology, zoology*), 2 points; Physical Science (chemistry, physics), 2 points; Trigonometery, 1 point; *Astronomy* (1), Civics (1), Geology (1), Physical Geography. (1), Physiology and Hygiene (1), Political Economy (1).

(*One point in any* subject in a high school or academic course demands not less than five periods per week of forty-five minutes each *for eighteen* weeks).

(*d*) Certificates from reputable instructors recognized by the [illegible] ter to be mentioned or by any state board [illegible] uly authorized by law, may be accepted in [illegible] examination.

Sec 2.—This examination must be conducted by or under the authority of the superintendent of public instruction of the city or state in which the college is located. In no case shall it be conducted by any person connected with the faculty, medical or otherwise, of the institution to which the student is seeking admission.

Sec. 3.—A student may be allowed to enter on his medical work conditioned in not more than six points, and these conditions must be removed by satisfactory examination before he is allowed to enter on the second year of his medical course.

Sec. 4.—Colleges in membership in this Association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of their course, but no member of this Association shall admit a student to advanced standing without first communicating with the college from which such student desires to withd[illegible] the dean of such college a direct written [illegible] to the applicant's professional and mor[illegible] the exact work he has done in said college.

Sec. 5.—Candidates for the degree of Doctor of Medicine shall have attended four courses of study in four calendar years, each annual course to have been of not less than thirty teaching weeks' duration, and at least ten months shall [illegible] beginning of any course and the beginnin[illegible] urse.

Sec. 6.—Credit may be given to the [illegible]. Degree from an approved college or university for any work in the medical branches which he has successfully completed in his college course, only so far as it is the full equivalent of corresponding work in the medical curriculum. The holder of such Bachelor's Degree may also be given time credits of not exceeding one year, provided that such student has had at least 40 hours in physics, 144 hours in chemistry, 24 hours in osteology, 292 hours in human or comparative anatomy, 124 hours in histology, 85 hours in embryology, 145 hours in physiology and 46 hours in materia medica; provided that the applicant for such time credits satisfies the professors of the chairs mentioned in the medical school as to his proficiency in these first-year medical studies, and satisfies the examiner, as provided for in Section 2, Article III, that his studies for which the degree was conferred include the above requirements. Such student may be allowed to complete a course for the medical degree in not less than 31 months, provided he completes the remainder of the medical curriculum in that time.

Sec 7.—A college which gives less than a four years' course of study, but does not graduate students, and is possessed of other required qualifications, may be admitted to membership.

Sec. 8.—Each student shall be obliged to attend 80 per cent. of the exercises in every annual course of study for which he seeks credit. No student shall be given credit on examination unless he attains a grade of at least 70 per cent. or its equivalent in any other marking system. And no student shall be graduated unless he shall have attained a passing grade in each and all subjects of the required curriculum.

ARTICLE V.

Section 1.—The entire course of four years shall consist of at least 4,000 hours, divided into the subjects as shown in the following table, and no college shall be recognized that falls below this standard over 20 per cent. in any one branch or over 10 per cent. in the total. Laboratory or clinic hours may be substituted for didactic hours.

* Information not obtainable.

progress in art, science and letters. (The examination to avoid exact dates and minor details.)

5. Latin Language. (a) Grammar; (b) four books of Cæsar, its equivalent.

The colleges recognized as in good standing by this organization are: Hahnemann Medical College of the Pacific; Denver Homeopathic Medical College; Hahnemann Medical College, Chicago; Hering Medical College; Homeopathic Medical Department of the State University of Iowa; Southwestern Homeopathic College, Louisville, Ky.; Kansas City Hahnemann Medical College; Southern Homeopathic Medical College, Baltimore, Md.; Boston University School of Medicine; Homeopathic Medical College of University of Michigan; Detroit Homeopathic College; College of Homeopathic Medicine and Surgery of University of Minnesota; Homeopathic Medical College of Missouri; New York Homeopathic Medical College; New York Medical College for Women; Cleveland Homeopathic Medical College; Pulte Medical College, Cincinnati; Hahnemann Medical College of Philadelphia.

The Secretary is Dr. Chas. Gatchell, 100 State St., Chicago.

NATIONAL CONFEDERATION OF ECLECTIC MEDICAL COLLEGES.

The following are the present minimum requirements for admission to colleges members of this Association:

1. Good English education, to be attested by (a) first grade teacher's certificate; or (b) a diploma from a graded high school, or literary or scientific college or university; or (c) regents medical students certificate; or (d) entrance examination covering a good English education including an elementary knowledge of natural history, physics and Latin.

2. Graduates from pharmaceutical, dental and veterinary colleges may be allowed one year's time on a four-year medical course, only on condition that they comply with the entrance requirements, and pass all examinations and perform all laboratory work embraced in the course of study of the Freshman year. One year's advanced standing may be given students with degrees from a recognized literary college.

3. The course of instruction shall consist of a four-year graded course or its equivalent, as herein prescribed, including four sessions of six months each in four *different calendar* years.

The following colleges are members of this confederation:

American Medical College, St. Louis, Mo.; Bennett College of Eclectic Medicine and Surgery, Chicago, Ill.; California Medical College, San Francisco, Cal.; Eclectic Medical College of the City of New York, New York, N. Y.; Eclectic Medical Institute, Cincinnati, Ohio; Georgia College of Eclectic Medicine and Surgery, Atlanta, Ga.; Lincoln Medical College, Lincoln, Neb.; Kansas City Eclectic Medical University, Kansas City, Mo.

The secretary-treasurer is John K. Scudder, M.D., 1009 Plum St., Cincinnati, Ohio.

States that Have no Medical School.—The following states and territories contain no medical college: Arizona, Delaware, Florida, Hawaii, Idaho, Indian Territory, Montana, Nevada, New Jersey, New Mexico, North Dakota, Porto Rico, Rhode Island, South Dakota, Utah, Washington, and Wyoming.

Philippine Islands.—Owing to the scarcity of physicians in the Philippine Islands, and also for the purpose of improving the present medical service, the Philippine Islands Medical Association, at its second annual meeting held in March, 1905, recommended the establishment of a modern school of medicine in Manila as a part of a general university.

Proposed Mergers.—It has been rumored that the Detroit College of Medicine will be merged with the University of Michigan with a view of teaching the last two years of the medical course at Detroit instead of at Ann Arbor.——Owing to the severity of the entrance requirements to medical colleges of Ohio, the number of matriculants fell off considably last year. This scarcity of pupils has brought about a revival of the talk of consolidating two and possibly three of the Cincinnati medical colleges into one big institution. Nothing positive has been done in the matter.

New College and Colleges Discontinued.—During the year only one new college has been formed, a most unusual occurrence. However, some changes of interest have taken place in the medical college world. The Kansas City Medical College, the Medico-Chirurgical College of Kansas City, Mo., and the College of Physicians and Surgeons of Kansas City, Kan., have been absorbed by the University of Kansas, and hereafter this institution will teach the four years of medicine. The first two years of the course will be given at Lawrence, the last two at Kansas City, Kan., Kansas City, Mo., and Rosedale, Kan., where a new hospital has been erected by authority of the state.——In St. Joseph, Mo., the Ensworth Medical College and the Central Medical College have combined, assuming the name of Ensworth-Central Medical College.——Dallas Medical College, Dallas, Texas, has been merged with the Medical Department of Baylor University of the same city.——Bell Medical College, Dallas, Tex., has changed its name to College of Physicians and Surgeons.——The Columbian University, Washington, D. C., is now known as the George Washington University.—The new college formed during the year is the Eclectic Medical Institute of Dallas, Texas. The Epworth University, Oklahoma City, Okla., which last year gave instruction in the first year of the medical course, now proposes to teach the full four years.——The Fordham College Medical Department, which was instituted last year, will open its first session in October, 1905.——The Medical Department of the University of Porto Rico has not yet been organized.——Harvey Medical College, Chicago, has ceased to exist.——Lombard College, Galesburg, Ills., has discontinued teaching the first year of the medical course.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Bronchial Asthma.

In considering the treatment of bronchial asthma *The Practitioner*, London, calls attention to the importance of distinguishing it from the other forms of asthma, such as cardiac asthma, renal asthma, hay asthma, thymic asthma or laryngismus stridulus due to enlargement of the thymus gland.

Bronchial asthma or spasmodic asthma is the condition in which there is a marked neurotic element and is caused by a sudden contraction of the unstriped muscular fibers in the walls of the bronchioles, which are innervated by the pneumogastric nerve. The spasms usually occur at night, accompanied by wheezing through the day.

The treatment, as described by the *Practitioner*, is arranged under two heads:

1. That to be resorted to during the attack.
2. That to be adopted during the intervals to prevent their recurrence if possible.

During the attack a little chloroform should be inhaled to produce rapid relaxation of the bronchial muscles. Cigarettes of stramonium leaves may be of service. A powder consisting of pulverized belladonna, *stramonium and hyoscyamus* leaves with some potassium nitrate burnt and the fumes inhaled will often bring relief. An inhalation of from three to *five minims* (.20-.30) of the nitrite of amyl from a crushed capsule frequently relieves the paroxysm. Between the attacks the following combinations, containing potassium iodid, *is recommended:*

℞.	Potass. iodidi	gr. x		65
	Tinct. lobeliæ	ʒss	2	
	Vini ipecacuanhæ	m. xii		75
	Aquæ chloroformi q. s. ad	℥i	30	

M. Ft. mistura. Sig.: Two tablespoonfuls three times a day after food. Or:

℞.	Potassii iodidi	gr. xii		75
	Ext. stramonii	gr. 1-6		01
	Spts. chloroformi	m. xx	1	30
	Spts. ammon. arom	m. xx	1	30
	Aquæ q. s. ad	℥ss	15	

M. Sig.: To be taken at one dose on retiring at night.

[Hypodermic injections of morphin with cocain, or morphin grain 1-3 (0.2) and atropin grain 1/100 (.066) are also recommended, but it is not advisable to use these drugs in this condition unless in extreme and aggravated cases after all other remedies have been tried.]

Two other considerations are of importance in the treatment of bronchial asthma. 1. The place of abode must suit the patient. High, dry altitudes are preferable in some cases, in others, the seaside, country, or city may best suit the individual. 2. The diet must be carefully looked after and regulated. Heavy meals should not be taken in the evening, as dyspepsia is often the starting point of an attack. Whisky and a few minims of the spirits of chloroform often relax the bronchioles and check an oncoming attack.

Other combinations containing lobelia are recommended by some authors as follows:

℞.	Tinct. lobeliæ ether	ʒii	8	
	Aquæ minth. pip	℥iv	120	

M. Sig.: One tablespoonful every half hour until relieved. Or:

℞.	Tinct. lobeliæ	ʒi	4	
	Tinct. belladonnæ	ʒi	4	
	Tinct. aconiti	m. xx	1	30
	Aquæ cinnamomi q. s. ad	℥iii	90	

M. Sig.: *One* tablespoonful every three or four hours until relieved.

Between the attacks the following may be given:

℞.	Potass. iodidi	ʒiiss	10	
	Potass. bicarb.	ʒv	20	
	Tinct. bellad.	ʒiii	12	
	Infus. gent. co. q. s. ad	℥iv	120	

M. Sig.: One teaspoonful in water three times a day, after food.

Stramonium may be administered during or at the beginning of an attack, combined as follows:

℞.	Tinct. stramonii	ʒiv	15	
	Tinct. aconiti	ʒii	8	
	Potass. bromidi	℥i	30	
	Aquæ chloroformi q. s. ad	℥iii	90	

M. Sig.: One teaspoonful in water at the beginning of the attack. Or:

℞.	Ext. stramonii	gr. vi		40
	Pulv. opii	gr. iv		25
	Camphoræ	gr. xx	1	30
	Mft. cap.	no. xii		

Sig.: One capsule three times a day.

High Arterial Blood Pressure.

H. D. Rolleston, in an article in the *Clinical Journal* (London), enumerates in a general way the following most important causes of high arterial tension:

1. Poison taken into the body, such as lead.
2. Autointoxication.
3. Imperfect elimination by the kidneys, skin or blood.
4. Nervous influences, such as worry and strenuous living.
5. Excessive influence of the adrenal glands.

The results of this continued high arterial pressure are hypertrophy of the left ventricle, atheroma, endarteritis and granular kidney.

The symptoms arising from such conditions are numerous, including mental weakness, senility, syncopal attacks, dilated heart, angina pectoris, granular kidney, pleural effusions, diabetes, loss of weight and neurasthenic conditions.

In the treatment of this important pathologic condition the cause in each case must be considered. The general conditions of life should be made simple and healthy. Food must be taken in moderation. Without becoming vegetarian, the author recommends less proteid and relatively more carbohydrate. Mastication should be thorough. Extreme moderation in the use of alcohol or total abstinence should be insured. Exercise, but not to excess, is very important in preventing high tension. The exercise should be taken regularly and in the open air. Passive exercise, or massage to the muscles of the limbs, lowers blood pressure and is of benefit in this condition. Superficial massage raises arterial tension. Elimination by the skin must be kept up and if necessary Turkish baths may be taken to dilate the peripheral vessels and thus lower the blood pressure. The reduction of blood pressure by medicinal means is a difficult task, according to this author. The number of drugs which will do this effectively is small and at the same time a too sudden reduction of blood pressure may produce harmful results.

The author calls attention to the danger of producing an irregular pulse and cardiac failure, as in one case, by the reduction of arterial pressure from 220 to 110 mm. of mercury, by administration of the tincture of aconite in five minim (.30) doses. Of the vasodilators, nitrite of amyl has only transient action, the nitrite of soda having a more persistent effect. In this connection, he states that it is highly probable that insufficient doses of these preparations are given and disappointment in the results follow.

The official dose of sodium nitrite is from one to two grains (.06-.12), but he quotes the use of this preparation in doses ranging from one and a half (.90) to five grains (.30) often repeated.

Spiritus Glycerylis Nitratis (U. S. P., Eighth Dec. Rev.) (1 per cent.) should be given in doses ranging up to ten minims (.65). The iodids are commonly employed to bring down the arterial tension, but in ordinary doses the author does not believe they have much effect unless by possibly stimulating the thyroid gland to increased secretion, and in that way reducing arterial tension.

Loomis recommends chloral hydrate in five grain doses (.30) as of more benefit than spirits of glyceryl trinitrate. Salines and small doses of mercurials are of value in preventing intestinal fermentation, the products of which, when absorbed, tend to constrict the blood vessels and to increase the arterial tension.

In Bright's disease, accompanied by high arterial tension, the following combination is of value:

℞. Nitroglycerini	gr. 1/4	015
Tinct. strophanthi	ʒii	8
Tinct. belladonnæ	ʒi	4
Elix. simplicis q. s. ad	℥iii	90

M. Sig.: One teaspoonful from every four to six hours until the effects on the pulse are shown.

N. S. Davis, in the *Sys. of Phys. Therapeutics*, recommends, when the arteries are sclerosed, that milk should form a considerable element of the diet, vegetables, breads, cereals, fruits and eggs moderately, fish, oysters and the white meat of fowls may be used.

The red meats, such as beef and mutton are the chief sources of alimentary toxins and should be eaten daily and should be entirely excluded from the diet if headache, insomnia, nocturnal distress, sighing respiration or dyspnea suggests autointoxication. When such symptoms arise, a milk diet should be prescribed for a few days or otherwise modified by the addition of cereals, bread and a small quantity of vegetables and fruits.

The necessity of eating sparingly rather than heartily is greater in proportion as the lesions of the arteries become more pronounced.

At all times pork and 'high' game, meat stews, rich gravies, greasy soup, preserved meat, crabs, and lobsters must be avoided.

Medicolegal

Liability for Performance of Unauthorized Operation.—The Supreme Court of Minnesota says that the question raised in the case of Mohr vs. Williams as to whether the consent of a patient is necessary to the performance of an operation is new in that state. At least, no case was called to the court's attention wherein it has been discussed or decided, and very few cases were cited from other courts. Continuing, it says that it has given the matter very deliberate consideration, and is unable to concur with counsel for the defendant in their contention that the consent of the plaintiff was unnecessary in this case. It can not be doubted that ordinarily the patient must be consulted, and his consent given, before a physician may operate on him. 1, Kinkead on Torts, section 375, states the general rule on this subject as follows: "The patient must be the final arbiter as to whether he will take his chances with the operation, or take his chances of living without it. Such is the natural right of the individual, which the law recognizes as a legal one. Consent, therefore, of an individual, must be either expressly or impliedly given before a surgeon may have the right to operate." There is logic in the principle thus stated, for, in all other trades, professions or occupations, contracts are entered into by the mutual agreement of the interested parties, and are required to be performed in accordance with their letter and spirit. No reason occurs to the court why the same rule should not apply between physician and patient. If the physician advises his patient to submit to a particular operation, and the patient weighs the dangers and risks incident to its performance, and finally consents, he thereby, in effect, enters into a contract authorizing his physician to operate to the extent of the consent given, but no further.

It was not, however, contended by the defendant that under ordinary circumstances consent is unnecessary, but that, under the particular circumstances of this case, consent was implied; that it was an emergency case, such as to authorize the operation without express consent or permission. The defendant was a physician and surgeon of standing and character, making disorders of the ear a specialty and having an extensive practice. He was consulted by the plaintiff, who complained to him of trouble with her right ear, and, at her request, made an examination of that organ for the purpose of ascertaining its condition. He also at the same time examined her left ear, but, owing to foreign substances therein, was unable to make a full and complete diagnosis at that time. The examination of her right ear disclosed a large perforation in the lower portion of the drum membrane, and a large polyp in the middle ear, which indicated that some of the small bones of the middle ear (ossicles) were probably diseased. He informed the plaintiff of the result of his examination, and advised an operation for the purpose of removing the polyp and diseased ossicles. After consultation with her family physician, and one or two other consultations with the defendant, the plaintiff decided to submit to the proposed operation. She was not informed that her left ear was in any way diseased, and understood that the necessity for an operation applied to her right ear only. She repaired to the hospital, and was placed under the influence of anesthetics; and, after being made unconscious, the defendant made a thorough examination of her left ear, and found it in a more serious condition than her right one. A small perforation was discovered high up in the drum membrane, hooded, and with granulated edges, and the bone of the inner wall of the middle ear was diseased and dead. He called this discovery to the attention of the plaintiff's family physician, who attended the operation at her request, who also examined the ear and confirmed the defendant in his diagnosis. The defendant also further examined the right ear, and found its condition less serious than expected, and finally concluded that the left, instead of the right, should be operated on, devoting to the right ear other treatment. He then performed the operation of ossiculectomy on the left ear, removing a portion of the drum membrane and scraping away the diseased portion of the inner wall of the ear. The operation was in every way successful and skillfully performed. But the plaintiff claimed that the operation greatly impaired her hearing, seriously injured her person, and, not having been consented to by her, was wrongful and unlawful, constituting an assault and battery. She obtained a verdict for $14,322.50 damages, but a new trial was granted on the ground that this was excessive.

The Supreme Court affirms the order granting a new trial, but holds that the defendant had no authority to perform the operation without the plaintiff's consent, express or implied. That her consent was not expressly given, and whether it should be implied from the circumstances of the case was a question for the jury to determine. That, if the operation was not authorized by the express or implied consent of the plaintiff, it was wrongful and unlawful and constituted in law an assault and battery. It is unnecessary to show in a civil action for assault and battery that the defendant intended by the act complained of to injure the plaintiff. It is sufficient if it appear that the act was unlawful.

The medical profession, the Supreme Court says, has made signal progress in solving the problems of health and disease, and they may justly point with pride to the advancements made in supplementing Nature and correcting deformities and relieving pain and suffering. The physician impliedly contracts that he possesses, and will exercise in the treatment of patients, skill and learning, and that he will exercise reasonable care and exert his best judgment to bring about favorable results. The methods of treatment are committed almost exclusively to his judgment, but the court is aware of no rule or principle of law which would extend to him free license respecting surgical operations. Reasonable latitude must, however, be allowed the physician in a particular case; and the court would not lay down any rule which would unreasonably interfere with the exercise of his discretion, or prevent him from taking such measures as his judgment dictated for the welfare of the patient in a case of emergency. If a person should be injured to the extent of rendering him unconscious, and his injuries were of such a nature as to require prompt surgical attention, a physician called to attend him would be justified in applying such medical or surgical treatment as might be necessary for the preservation of his life or limb, and consent on the part of the injured person would be implied. And, again, if, in the course of an operation to which the patient consented, the physician should discover conditions not anticipated before the operation was commenced, and which, if not removed, would endanger the life or health of the patient, he would, though no express consent was obtained or given, be justified in extending the operation to remove and overcome them.

But such was not the case at bar. The diseased condition of the plaintiff's left ear was not discovered in the course of an operation on the right, which was authorized, but, on an independent examination of that organ, made after the authorized operation was found unnecessary. Nor was the evidence such as to justify the court in holding, as a matter of law, that it was such an affection as would result immediately in the serious injury of the plaintiff, or such an emergency as to justify proceeding without her consent. She had experienced no particular difficulty with that ear, and the questions as to when its diseased condition would become alarming or fatal, and whether there was an immediate necessity for an operation were, under the evidence, questions of fact for the jury. The evidence also made the qeustion of whether, if the family physician by his conduct assented to the operation, the plaintiff was bound thereby, one of fact for the jury to determine.

The amount of the plaintiff's recovery, if she was entitled to recover at all, must depend on the character and extent of the injury inflicted on her, in determining which the nature of the malady intended to be healed and the beneficial nature of the operation should be taken into consideration, as well as the good faith of the defendant.

7 *The Busy Practitioner from a Business Point of View. A. J. Colton, Buffalo, N. Y.

2. **Why Surgical Fixation of a Movable Kidney Will Not Relieve Dyspeptic and Nervous Symptoms.**—Aaron says that the study of several hundred cases in his own practice has led him to the belief that movable kidney in itself can not produce all the dyspeptic and nervous symptoms of which patients complain, unless there is a displacement of some other organ in the abdomen. Cases in which the kidney alone is movable are those that give few or no symptoms. The author's results in over 600 cases, with a properly fitting band, have proved eminently satisfactory. Before fitting a band to patients with movable kidney, the location of all the abdominal organs must be accurately made out by palpation, auscultatory percussion, transillumination, inflation, *x*-ray, etc. A movable kidney is only pathologic when it is palpable. The irrationality of producing a pathologic condition by fixing a kidney that ought to be mobile, therefore, can readily be seen. When a patient is in the dorsal decubitus position, gravity carries the kidney back to its normal position. This can not take place when a kidney is surgically fixed, and under these circumstances there is always an abnormal condition. In cases of movable kidney, surgeons irrationally endeavor to bring about an abnormal adhesion, and in this way induce a condition that may aggravate the symptoms they are endeavoring to relieve.

3. **Management of Transmissible Diseases.**—Bergey says that the general prevalence of some of the transmissible diseases may be attributed to two important causes: (1) The infection of large numbers of individuals through mild and often unrecognized cases; and (2) the failure to enforce the sanitary precautions that would prevent the dissemination of infectious materials. The difficulty experienced in the satisfactory isolation of cases of transmissible disease in private houses calls for the more general treatment of these diseases in proper isolation hospitals. There are at least four important sources of danger from such hospitals, yet with proper equipment and management all these dangers may be eliminated. They are (1) the danger of the dissemination of infectious materials through the drainage; (2) the danger of the dissemination of infectious materials by means of air currents; (3) the danger of the dissemination of infectious materials by insects or vermin; (4) the danger of the dissemination of infectious materials by the physicians, nurses, attendants, visitors, or the convalescents.

4. **Hypnotic Cumulative Action as a Therapeutic Guide.**—Butler discusses the principle of aggravation of symptoms from the standpoint of therapeutic indication, so far as hypnotics are concerned. The cumulative effects of the hypnotics, as shown by their extreme effect hours after their first administration, indicate that this can be secured by broken doses given at intervals, so as to secure the acme of influence during the hours after 12, midnight, when this influence is most needed. The various alterative effects of the hypnotics serve as an indication that they will counteract the effects occasioned by the products of altered metabolism which are irritating the monarchical vasomotor center of the medulla. The synthetics, which are more potent in these particulars, can be aided, and their injurious effects removed by the addition of vegetable hypnotics, like conium, and those derived from the solanacea, as well as certain opium derivatives.

6. **Arteriosclerosis.**—Stockton states that heredity, together with syphilis, alcohol, gout, etc., are, in his opinion, the most prominent etiologic factors. He discusses the pathologic changes in the blood vessels and calls attention to the symptoms in the various forms of the disease, particularly the cardiac form. He directs attention to renal sclerosis, and regards chronic interstitial nephritis as an important cause of the cardiac form of the disease and also of sclerosis of the encephalon. The importance of recognizing the disease in the early stages is emphasized and treatment is fully discussed.

7. **The Busy Practitioner from a Business Point of View.**—Colton has devised a card index system, whereby a physician can keep his own books as easily as he can keep the ordinary visiting list.

13 *Fibroma of the Ileum, Producing Obstruction by Invagination; Enterotomy; Recovery. H. A. Royster, Raleigh, N. C.

8. **Syphilitic Spinal Paralysis.**—According to Dougherty, the time that has elapsed between the primary infection and the onset of symptoms indicating medullary involvement must be taken into consideration, and those cases developing within a few years after the luetic infection, even though slow in onset may be looked on as an expression of secondary or tertiary syphilis, whereas, if a considerable period of time has elapsed before the beginning of the symptoms referable to the cord, the changes must be due to what he calls the terminal syphilitic stage. He describes the histories and pathologic findings in two cases of the former class, which lead him to conclude that it is the distribution and dissemination of the vascular lesion rather than any special difference in their nature which determines which type of spinal syphilis shall ensue, and that the so-called Erb's syphilitic spinal paralysis is *not*, as Erb is inclined to believe, necessarily dependent on a system disease of the spinal cord.

9. **Copper, Zinc and Brass Poisoning.**—Sicard describes the technical processes employed in the production of copper, zinc, and brass, and the toxic effects to which the workmen engaged in them are subject.

10. **Rheumatism of Feet.**—Ely says that among the patients seeking relief at an orthopedic clinic probably the most frequent complaint is "rheumatism of the feet." There is no "rheumatism of the feet." One of the commonest affections giving rise to pain in the feet is flat foot. Another is anterior metatarsalgia, or Morton's toe. Gonorrheal arthritis or periarthritis of the ankle has often been observed, and the author says that there is a form of gonorrheal infection characterized by extreme sensitiveness about the sole, to which he gives the name of gonorrheal foot. The pathology of this affection is still a matter of doubt. Hysteria may simulate rheumatism of the feet, and tuberculosis of the ankle and tarsus must also be carefully excluded, as any circumscribed, persistent, painful swelling in the foot, especially of a child, is to be viewed with extreme suspicion. The sequelæ of fractures, and the pains of late syphilis or of locomotor ataxia must also be kept in mind.

Gout and acute rheumatism itself close the list of such affections, and it is pointed out that acute articular rheumatism never leaves behind it a damaged joint. The treatment of these conditions is briefly outlined, the chief adjuvants required being zinc oxid plaster, plaster of Paris, a few drugs, and some assistance from the bracemaker and shoemaker.

11. **Gases of Body.**—Watson says that some of the gases, like oxygen, nitrogen, and carbon dioxid, are essential to our existence, but others are waste products, and appendicitis, intestinal obstruction, ovarian disease and heart troubles may be simulated by their presence in the intestinal tract. Nitrogen, oxygen, carbon dioxid, sulphureted and carbureted hydrogen, and marsh gas are the principal gases of the body. Carbon dioxid is the greatest in volume and the most widely diffused. It has usually been designated as a poisonous gas, but modern physiologic chemistry takes a different view of it, and it can be considered poisonous only when it is an obstruction of respiration. Large amounts may be found in the stomach and bowels in health, and still more in neurotic conditions, but its coefficient of absorption is high and but little inconvenience results. The accumulation of gas in the bowels may give rise to diagnostic difficulties, and the author cites several such cases. Lactic, acetic, and butyric acid fermentation, and the decomposition of fats, proteid matter and cellulose are all concerned in the formation of intestinal gases. When loops of gut are strangulated, first water and later gas forms in them, giving rise to meteorism. Phantom tumors are of this order. Headache, vertigo, and nausea are often the result of the presence of sulphureted hydrogen in the bowel. The formation of intestinal gases must be controlled by proper management of the diet.

12. **Importance of Early Recognition of Valvular Disease in Children.**—Childs speaks principally of valvular disease of rheumatic origin. He defines rheumatic endocarditis by saying that it is an inflammation of the lining membrane of the heart commonly confined to the valves, manifested by stiffness or pain in the joints or tendon sheaths, or in any of the muscles of the body, from the most trivial or obscure form to a well-marked arthritis. It is usually accompanied by rapid heart action without regard to intermittency or irregularity, a low grade of fever, ofttimes but a half degree, a soft blowing, usually systolic murmur at the apex of the heart, and by a well-marked leucocytosis. He calls attention to the necessity for careful physical examination of children, emphasizing the fact that endocarditis in children is very often overlooked in its early stages because the manifestations of rheumatism in children are usually very obscure. They may appear only as the so-called wandering or growing pains, or there may be only stiffness, or definite joint pains alone, or joint pains plus swelling and redness. Any muscular pain, no matter how slight or where located, may mean an associated endocarditis. In the treatment especial attention must be paid to the heart muscle by rest and general systematic treatment to prevent anemia and malnutrition.

13. **Fibroma of Ileum, Producing Obstruction by Invagination.**—Royster gives the history of a man of 42 who for about six months had suffered from symptoms pointing to a progressive growth of the intestine. Finally there came an attack of obstruction, which on opening the abdomen was found to be caused by an invagination of the ileum secondary to the presence in the gut of a pedunculated fibroma, the size of a walnut. This was removed through a longitudinal incision by excising the ellipse of mucous membrane surrounding its base, and the intestinal wound closed with three rows of continuous sutures of silk, one for each coat and an extra interrupted Lembert stitch on the peritoneal coat. The patient made a good recovery.

15. **Galvanism in Neurology.**—Pritchard is convinced of the efficacy of galvanism in neurology, though it is by no means indiscriminately applicable. On the contrary, its field is relatively limited, and it has no place as yet in the numerical majority of neurologic cases, or, if a place at all, only as an aid in some collateral way to the end desired. In the field of peripheral nerve diseases, including many of the neuroses, nearly all forms of neuritis, the tics, vasomotor and trophic affections, and the paresthesiæ of whatever cause, galvanism occupies a position of positive and indispensable importance. The fatigue psychoses, the headaches and cerebral conditions underlying the obsessions of neurasthenia, and of simple affective melancholia, are really the field of selective usefulness for this agent. Even in this field of selection, however, galvanism is rarely, if ever, a specific. To get the best results, it is necessary to have a proper equipment and to know how to use it.

16. **Appendicitis.**—Kime says that the average surgeon will save more lives by operating only in the severe cases of appendicitis within the first forty-eight hours and in those in which the patients suddenly grow worse after a few days of improvement; doing the interval operation on all patients who do not completely recover from first attack and in relapsing cases. Internal treatment properly conducted should have a death rate of not over from 2 to 5 per cent. The death rate can be reduced nearest to zero by the average surgeon doing the interval operation on those patients who do not fully recover or who have relapses, and operating in the severe cases within from twenty-four to forty-eight hours and in those that suddenly grow worse after a few days of improvement, leaving the remainder of the cases to judicious medical treatment. There is also a field for medical treatment in many cases after the appendix has been removed in correcting the original cause of appendicitis or looking after existing complications. The surgeon should not dogmatically assert that appendicitis has no medical treatment, nor decry or exclude judicious medical treatment in these cases; neither should the general practitioner exclude the surgeon, but each should assist the other.

18. **Stricture of Urethra.**—Pedersen calls attention to a tunnelled and grooved sound and catheter devised by him. The curve of the sound is of the same radius as the standard urethral sound, but one inch shorter. This decrease in length has been compensated for by an increase of one inch in the length of the shank. The object and advantage of the short curve lie in the fact that there is very much less leverage on the face of a stricture in a short curve than in a long curve, thus the danger of injuring the filiform and of making false passages in the urethra is greatly decreased. The taper of the curve is uniform from its base to its tip and regularly includes six sizes from No. 12 F. upward. The smallest point of the instrument is made 6 F. for the reason that this is the size of the Maisonneuve instrument. The small sizes, therefore, below 12 F. are uniformly at the tip No. 6 F. and regularly taper upward as follows: Two sizes for 8 F., three sizes for 9 F., four sizes for 10 F. and five sizes for 11 F. The uniformity of the taper has the object of rendering the dilatation much more secure on the following grounds: The middle of the curve of the 21 F. sound, for example, is 18 F., while the sizes 19 and 20 F. occur at equal distances between the middle of the curve and the full size of the shank. If, therefore, a No. 20 F. sound has already been passed through the stricture, the beak of a 21 F. sound will be almost entirely through the same stricture before the dilating begins. The safety of this plan is obvious and becomes much more important when, for any reason, the dilating is being done more rapidly than one size at a time. The tunnel of the sound is one-third larger in diameter than the diameter of a small filiform and is five-eighths of an inch long. These dimensions are uniform throughout the set of sounds, thus securing entire uniformity of action and correcting the mistake in the standard tunneled sound by which the tunnels in the upper sizes are so large as to permit an inconvenient amount of play over the filiform. The length of

the tunnel secures the sounds from twisting, buckling, breaking or cutting the filiforms, accidents which are not infrequent in the standard instrument. The length, however, is not sufficient to cause binding of the sound on the filiform, provided ordinary skill is employed. The groove of the sound passes along the shank three-quarters of the length thereof, thus insuring ease of testing the freedom of the filiform. The grooves, like the tunnels, are also of the same size and length throughout the set. There is no reason whatever for increasing the width and depth thereof as the size of the sounds advances, thus the inconvenient dipping of the mucous membrane into a wide groove in a large sound is largely corrected and consequent pain to the patient avoided. The tunneled and grooved silver catheter alluded to in the title are designed in the same manner, namely: With a short curve of uniform taper of six sizes, a shank one inch longer than the standard, tunnels of uniform diameter, five-eighths of an inch long, and grooves of uniform length, depth and width throughout the series. The set which the author has employed consists of a 6 F., 12 F. and 18 F., tunneled and grooved catheter and sounds of all numbers from 8 to 20 F., both inclusive, also 22 and 24 F. The ordinary practitioner can do perfectly good work with catheters 6 and 12 F. and the even numbered sounds from 8 to 20 F., both inclusive. Only the specialist who is certain to encounter difficult cases frequently needs every size of sound. The technic of employing these instruments is as follows: After the filiform has been inserted in the usual manner, the 6 F. catheter is passed over the filiform, the bladder, if distended, is partially evacuated through the silver catheter or, if empty, is moderately filled with any mild antiseptic solution, such as boric acid, permanganate of potash, Thiersch or silver nitrate solution. The catheter is then removed, leaving the filiform *in situ*, and the sounds are taken in order, beginning with 8 F., and gently passed over the filiform through the stricture until that size is reached which the patient states to be moderately painful. Pedersen finds that, as a rule, most strictures may be thus dilated to about 10 F. with very little inconvenience to the patient. The sound is then left *in situ* for ten or fifteen minutes in order to get the full benefit of the dilatation. After this the filiform and sound are removed and the patient is allowed to evacuate the contents of his bladder. If the contents of the bladder be urine, as in cases of distention, the sound is removed and the filiform is left in place, and the silver catheter is then again passed and the bladder carefully washed with rather hot antiseptic fluid, some of which is left in the bladder to prevent bleeding, such as sometimes occurs when an overdistended bladder is emptied. After four or five days the patient returns for the passing of larger sounds. Usually in from four to six weeks dilatation is carried to the point where a filiform becomes unnecessary. A very few strictures are so tortuous and deeply seated that tunneled and grooved sounds 22 and 24 F. should be passed over a filiform before use of the latter is abandoned.

27 Suggestions in Treatment of Wounds. H. D. Collins, New York.

21. **Tuberculous Peritonitis.**—As the result of personal experience and a study of the literature, Shober concludes that until we have more precise methods of differentiation most patients with tuberculous peritonitis will be operated on under some other diagnosis. Celiotomy and removal of the primary focus of the disease offers the best prospect of cure. The abdomen should be thoroughly irrigated and closed without drainage. A short course of *x*-ray treatment immediately following operation is advisable in all cases, but it is especially important in those cases in which the primary focus has not been removed. Should recurrence take place in these cases, a secondary operation—to remove, if possible, the primary focus—is advisable; and this operation should be followed by a course of *x*-ray treatment.

22. **Aluminum Corset in Pott's Disease.**—Ogilvy favors the aluminum corset, made from sheet aluminum of various thicknesses. To make an aluminum corset, a plaster of Paris cast of the body is taken. This is made exactly as is a plaster of Paris corset, except that the trimming of the upper and lower edges is omitted. Around this, after it has been removed from the body, an additional bandage is tightly wound, from top to bottom, drawing it closely together. This is then filled in with soft setting plaster of Paris. The outer cast of bandages is then removed and the model obtained over which the aluminum is molded. The hammering of the aluminum, in working it up to fit the model, so tempers it as to make it almost as durable as steel. It is made in two halves, which are swung from behind on two double-hinged joints. It is then perforated and polished. This makes not only a light, durable, comfortable and firm support, but also one which can be easily remodeled from time to time as occasion requires, and for this reason particularly is it of the greatest usefulness in spinal curvature, for it allows us to keep up a firm, even, constant pressure against the deformity without pain or discomfort. Before the cast for a corset is made, the rigidity and spasm of muscle, if present, should be as much as possible relieved to obtain a better correction of the deformity. This may be accomplished by manipulation and extension, which should be employed for several weeks, if necessary, previous to the application of the corset. The results obtained by the use of the aluminum corset with corrective exercises are these: Not only are the general development, health and muscle tone much improved, but the deformity is arrested, and to some extent—in some cases to a very great extent—corrected.

23. **Management of Summer Diarrheas in Children.**—Sill summarizes his views as follows: First, absolute rest for the inflamed mucous membrane of the stomach and intestines, attained by stopping all food and giving nothing but water; second, eliminate the cause—namely, a foreign substance which is causing irritation, as fermenting or indigestible food, this being done by the use of castor oil or calomel; third, success lies in the mode of gradually increasing the strength and quality of milk, beginning in all cases irrespective of the age up to a year with a very weak cream mixture.

6 Report of Speci[illegible]

2. **Opsonic Power of the Tuberculous.**—Urwick studied the opsonic power of the blood of 54 people suffering from various tuberculous affections, employing the method described by Wright, and found that this power may be either high or low. A low power is due to an inherent deficiency or to an exhaustion of the machinery of immunization. A high power is due to an active response by the machinery of immunization to the stimulus of infection. This power in the tuberculous varies from day to day, and the curve thus produced shows in many cases negative and positive phases following autoinoculation. The opsonic power of healthy people is nearly the same and does not vary from day to day.

4. **Perception of Light and Color.**—Edridge-Green attempts to show how his theory of light and color perception explains known facts of light and color vision. He assumes that light falling on the eye liberates the visual purple from the rods and a photograph is formed. The decomposition of the visual purple by light chemically stimulates the ends of the cones and a visual impulse is set up which is conveyed through the optic nerve fibers to the brain. These visual impulses probably differ in character according to the wave length of the light causing them. The author has examined the retina of several monkeys after they have been kept in a dark room and found that the visual purple was in the yellow spot between the cones. He discusses the evolution of the color sense, color blindness, color mixing, color vision of the periphery and of the retina, and color contrast.

9. **Influence of Feeding on Infant Mortality.**—Howarth has investigated this question in the case of 8,348 children, 63.3 per cent. of whom were breast fed, 19.5 per cent. hand fed and 17.3 per cent. breast fed at first and afterward hand fed, or partly breast fed and partly hand fed. The highest death rate (197.5) was observed among the hand fed children. It was nearly three times that recorded among breast-fed children (69.8), and twice that of children reared partly by hand and partly naturally (98.7). Among hand-fed children, diarrheal diseases and deaths from defective nutrition prevailed. Next in importance are chest ailments and then convulsions due to disorders of digestion. Among breast-fed children the most common causes of death are bronchitis, pneumonia and convulsions. Among children who were first breast fed and subsequently hand fed the death rate is not so high as among the purely hand fed, although the aggregate mortality is considerably higher than that of breast-fed children; in one or two diseases the mortality is lower. This result obviously points to the advantages which accrue to children who have natural food supplemented by artificial food rather than an entire supply of the latter. Children fed on condensed milk show a very high mortality, 255 deaths per 1,000 children. Next come the children reared on bread, rusks, arrowroot and other farinaceous foods, 252 per 1,000. The deductions made by Howarth are as follows: The use of sweetened condensed milk, either whole or skimmed, invariably should be discouraged and whole unsweetened condensed milk only should be permitted when one is satisfied that the milk is being used with a proper degree of dilution and with the necessary additions as in the case of modified cows' milk; also that since the death rate among children reared on patent foods is, on the average, higher than among those fed on diluted cows' milk, every attempt should be made to encourage parents to use this latter food and to educate them to an appreciation of the necessity for the additions to, and the dilution of, cows' milk to render it suitable for infant's food. The addition of patent foods to the dietary of very young infants is unnecessary, sometimes dangerous, and always expensive. Furthermore, it must not be forgotten that the risks to which hand-fed children are exposed are considerably minimized by mixed feeding and that, therefore, every mother who is unable fully to satisfy her infant should be encouraged to continue to feed her child and to supplement any deficiency by means of artificial food, and that only in case of absolute necessity should resort be had to artificial feeding alone.

11. **Practical Value of Grocco's Paravertebral Triangle in Pleural Effusions.**—Ewart recommends observance of this sign in cases in which the size of the pleural effusion is less than a fifth of that of the pleura. Whenever fluid collects within a free pleura, a paravertebral patch of partial dullness, triangular in outline, is obtainable in the other, the "dry," pleura. The crucial proof employed to test the genuineness of the trianguar dullness is its disappearance when the patient assumes the lateral decubitus on the side of the effusion, and its reappearance immediately he sits up or turns on to the sound side. This is at the same time a demonstration of the significance of the dullness, and is sufficient proof that its production is due to the influence of a mobile fluid. When, however, the pleura is overdistended, the mobility of the fluid is much reduced. The complete disappearance of Grocco's triangle does not then seem to occur, but the height of the triangle becomes much less with the change to the lateral posture. If there is no Grocco triangle of dullness there can be no free effusion in the chest. The extent of the effusion can also be determined by this sign; for, whereas the base of the triangle, corresponding in position to the twelfth rib and to the pleural sinus, varies only slightly with the bulk of different effusions, the length of the vertical side of the triangle varies exactly with the upper limit of the effusion.

13. **Digestive and Other Actions of Fruits.**—In this article Sharp shows that many common fruits contain ferments which play the part of papain and bromelin (ferment of pineapple), and that they can digest both egg and serum albumin to some limited extent. The fruits experimented with were strawberries, cherries, oranges, pears and apples. To obtain most benefit from the succulent fruits they should be eaten at the end of the chief meal. Stewed fruit, as a stimulant to the lethargic gut in constipation, should be eaten half an hour before breakfast. Oranges, if peeled and cut into thin slices and with castor sugar strewn over them, are highly efficacious as an aid to digestion. Grapes should only be eaten at the end of the chief meal of the day.

14. **Oral Sepsis as a Cause of Iritis.**—Campbell urges that the constitutional treatment of iritis should be directed to the removal of oral sepsis, for although about 50 per cent. of cases of iritis are undoubtedly due to syphilis, there is even here the possibility of a mixed infection. He has seen three cases of iritis in which there was an absolutely negative history of either syphilis or rheumatism in any shape or form, but in all three there was marked evidence of oral sepsis. The teeth were scaled, filled or extracted, suppurating pockets were purified and the mouth was rendered as pure as possible. This, combined with the use of mydriatics and tonics, cured all three patients rapidly.

17 Movable Displacement of the Kidney. D. Newman.
18 Treatment of Endometritis. J. K. Kelly.

15. **Secondary Perineorrhaphy.**—Cullingworth describes a secondary operation for complete rupture of the perineum which he has employed for many years. The operation appears to be a modification of Lawson Tait's. Having made lateral traction with the fingers on each side of the anus so as to efface the appearance of a triangle, forming a single, tense, transverse white line, Cullingworth plunges one blade of a pair of angular scissors deeply into the tissues of the rectovaginal septum at the left extremity of this white line,

dividing the septum into two layers from one end of the white line to the other. From each extremity of this first incision a cut is made, running forward, and another running backward, the whole series of incisions representing the letter H. The forward incisions will mark the outer boundaries of the vaginal flap, and their length will determine the length of the new perineum. It will generally suffice for these incisions (which are carried along the line at the sides of the vulva where skin and mucous membrane meet, or, to be more exact, where the skin alters in character) to be made to terminate where scar tissue ends, i. e., where the original perineum ended. If this is difficult to recognize, it will usually be safe to let them terminate where the labia minora commence. The two backward cuts are much shorter. Their object is to facilitate (1) the exposure and (2) the union of the divided ends of the sphincter. The completion of the vaginal flap may be accomplished either with the scissors or with the knife, the left forefinger being on guard in the vagina. The line of reflection of the flap should be nearly horizontal, and should extend completely across from the anterior end of one lateral incision to the anterior end of the other. Lateral traction is now removed, when the triangular shape of the gap in the torn anterior wall of the rectum again becomes apparent. This gap will be represented in the flap which has been dissected up. Care must be taken not to carry the anterior border of the new perineum far forward. The first suture passed is the buried perineal suture. The perineal needle is introduced into the skin about one-sixth of an inch from the margin of the denuded surface at a point immediately below the angle of reflection of the vaginal flap. It is passed completely round from one side to the other in the substance of the rectovaginal septum just above the line of reflection of the flap, and the point is made to emerge on the right side at a spot corresponding to the aperture of entrance on the left side. The needle should not, during its course, make its appearance either in the rectum, in the vagina or in the wound. The suture should be a buried suture throughout. Its use is to brace up the whole perineum and to prevent spaces being left in the deeper part of the wound, where the raw surfaces are not in contact, and in which fluids can accumulate. In cases in which no such spaces seem likely to occur, the buried suture may be dispensed with. When the needle has been successfully passed the eye is threaded with a stout silkworm-gut suture and the needle is withdrawn, the suture being left in position but not tied. The rectal tear is now sutured from above downward, the sutures being introduced by means of a full-curved needle, held in a firm needle-holder, at the edge of the rectal mucous membrane on one side of the rent. The point of the needle is brought out on the denuded surface at a point distant about half an inch from the point of entrance, in order to insure the inclusion in the stitch of a sufficient amount of tissue. It is then carried across to enter at a corresponding point in the raw surface of the opposite side, and to emerge at the margin of the rectal mucous membrane at a point exactly opposite the original point of entrance. The needle being now removed, the suture is tied and the ends are dropped into the rectum before the next suture is introduced. Two, three or four other sutures, according to the requirements of the case, are then introduced in the same manner, care being taken that the ends of each suture, as it is tied, are dropped into the rectum and kept back out of the way. Cullingworth always uses catgut for the rectal sutures, so that it may not be necessary to disturb the parts for their removal. When all have been introduced and tied, and not before, the ends may be cut off at the anus. The vaginal side of the laceration is now closed by means of a series of interrupted sutures of silkworm gut, the ends of which are left long so that they can be loosely tied together and turned into the vagina, whence they can be easily withdrawn for removal. The remaining perineal sutures, stout silkworm gut, are introduced through the skin at the same distance from the edge as in the case of the buried suture, about one-sixth of an inch. These sutures are made to pass deeply, and they remain almost, but not completely, buried. They cross from one raw surface to the other at the deepest part of the wound, and emerge at a point on the skin of the opposite side exactly corresponding in position to the point of entrance. The number required varies; usually it is three or four. Cullingworth generally passes them in order from before backward, leaving them untied until all have been passed. The tying is done in reverse order, viz., the hindmost first. This hindmost stitch should bring together the ends of the anus. Immediately before the perineal stitches are tied the wound receives a final irrigation and cleansing. The closure of the perineal wound will have the effect of completing the folding on itself of the vaginal flap, and the edges of the flap should be united by interrupted silkworm-gut sutures, continuing forward, as it were, the row of perineal sutures, but not passing them so deeply. Now is the time to introduce any superficial sutures that may be required in order to bring the edges of the skin neatly together. Sometimes no such sutures are required; sometimes three or four. Cullingworth is in the habit of leaving the ends of the perineal sutures long and tying them loosely together in a bunch. The advantages of this are as follows: 1, It adds to the patient's comfort by avoiding the pricking of the skin by the ends of the sutures, which almost always happens when they are cut off short; 2, if any dressings are necessary they can be applied much more easily than when the sutures are cut short; 3, it greatly facilitates the removal of the sutures, for, when the time comes for this to be done, the sheaf is untied and each suture in turn is slightly pulled on by means of its long ends, so that the knot can be easily made visible and the suture divided. The less elaborate the dressing of the newly-repaired perineum the better. Two little strips of lint, three inches long by three-quarters of an inch wide, anointed with vaselin and laid parallel with each other on each side of the wound, are all that is required. When the thighs, now flexed on the abdomen, come to lie in their natural position, these two bits of lint will be found to have their unanointed surfaces in contact, the bunch of perineal sutures projecting between them. It is quite obvious that the less interference there is with the newly united parts the better. Vaginal douching should be ordered only when there is a purulent or offensive discharge. Otherwise the internal parts should be kept clean by means of wool sponges and warm water. This local cleansing and changing of dressings can be done with least disturbance of the patient by flexing the legs on the thighs and the thighs on the abdomen in such a way as to afford a full view of the wound. If the patient can not, by grasping each leg under the knee, hold the limbs sufficiently out of the way for the nurse's purpose, the nurse should have an assistant support the heels of the patient while the wound is being attended to. The catheter is usually required for the first two or three days. As soon as the patient is able to dispense with the catheter she should do so. The patient must remain in the recumbent posture absolutely for at least fourteen days. A full dose of castor oil is administered sixty hours after the operation. If it has not acted in four hours the dose should be repeated. The perineal stitches are removed on the eighth day.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A CONSIDERATION OF THE ETIOLOGY AND DIETETIC TREATMENT OF INFANTILE ATROPHY.

A. H. WENTWORTH, M. D.

Assistant Physician to the Children's Hospital and to the Thomas Morgan Rotch, Jr., Memorial Hospital for Infants.

BOSTON.

INTRODUCTION.

The condition known as infantile atrophy, athrepsia, or marasmus occurs so frequently and its consequences are so serious that it is of the utmost importance to obtain accurate knowledge of its pathology and nature, in the hope that such knowledge may furnish indications for treatment. The clinical manifestations have been described so many times that it is unnecessary to refer to them here, more especially as any physician in general practice must have seen such cases.

The condition begins, as a rule, in the first two or three months of life, and is caused by errors in the diet. It may be that the quantity of food is excessive, that the quality of the food is unsuitable, or that the food is given too frequently. As a rule, one finds a combination of several errors. In consequence of faulty diet, the digestion, as is shown by the character of the dejections, becomes impaired. The infant does not gain in weight as it should. In most cases there is a loss of weight down to a certain point, and after this the weight may remain more or less stationary for weeks or for months. A distinction has been made between these so-called primary cases, which occur in the first few weeks of life, and cases presenting the same symptoms and following the same course, which begin later in infancy in consequence of some acute disease, especially severe acute gastroenteric disturbance. Neither clinically nor anatomically can the cases be distinguished from one another, and there appears to be little reason for classifying them separately. This statement is not meant to include cases in which the emaciation is associated with chronic diseases, like tuberculosis and syphilis.

THEORIES OF CAUSATION.

The way in which a faulty diet produces a condition of atrophy is still unknown. It was assumed by Nothnagel[1] and later by Baginsky[2] that a more or less constant derangement of digestion in these cases ultimately caused atrophy of the intestines; consequently absorption became so much impaired that a general wasting of the body tissues ensued. In support of this view, Baginsky produced drawings illustrative of the microscopic appearances of the intestines in such cases. Heubner[3] denied the correctness of these observations and claimed that the microscopic appearances described by Baginsky were due to postmortem changes and to artefacts. He said that the loss of epithelium was due to postmortem alterations and showed that any obliquity in the cross-sections of intestines produced the appearance of shallower ducts, and that the thinness or thickness of the wall could be modified by the degree of distention or contraction of the intestines. In this way, areas of atrophy and hypertrophy were simulated. He exhibited photographs of sections of normal intestines distended and cut obliquely which were similar to the appearances described by Baginsky in cases of atrophy. Heubner believed that the condition of atrophy was due to severe functional disturbance. Heubner's views were sustained by the work of Gerlach,[4] published about the same time. In Gerlach's cases, a condition similar to that described by Baginsky was produced by means of postmortem alterations and varying degrees of distention and contraction of the intestines. Two years later Habel[5] published the results of investigations of this subject carried on under the supervision of Ribbert. There was scarcely a suggestion of atrophy of the intestines in the cases which he examined, and the results of his experiments on animals confirmed the statements of Heubner and of Gerlach.

Bloch[6] recently published the results obtained by him from the examination of three cases of infantile atrophy. Postmortem changes were avoided by injecting a quantity of 10 per cent. formalin solution into the peritoneal cavity immediately after death. Measurements were made of the stomach and intestines. Great care was exercised in the fixation and handling of the specimens. Serial sections were made of the tissues, and modern methods of staining were employed. There was no evidence of intestinal atrophy. The only abnormality to which he attached any importance was the condition of Paneth's cells. These cells, described by Paneth[7] in 1888, are found in Lieberkuhn's ducts. Under normal conditions, the presence of certain granules in the protoplasm of these cells is accepted as evidence that they are functioning. In Bloch's cases of atrophy the granules in the Paneth cells were, for the most part, absent, and from this Bloch concluded that the cells were not functioning. There was no appearance of degeneration of

Paneth's cells. Bloch attached great importance to the condition of the cells as a causative factor in the production of infantile atrophy. He referred to Pawlow's work on digestion and the important part which the "succus entericus" plays in assisting pancreatic digestion. Bloch also referred to work previously done by him in which these cells were always found to be normal under a variety of pathologic conditions involving the intestines. He also referred to Paneth's experimental work on animals in which these cells presented no abnormal appearances even after prolonged starvation. Whether or not the condition of Paneth's cells in these cases actually causes the atrophy, he at least feels sure that the condition of these cells is a primary one and is not induced by the atrophy.

Bloch, in describing the liver changes, says that in no case did he find any inflammatory or cirrhotic changes. The acini were distinct and the bile ducts were normal. In two cases the liver cells were normal. In one case, the protoplasmic outlines were not distinct and many of the cells were filled with fat, but the nuclei stained well. Bloch mentioned that Gaston,[6], Lesné[9] and Merklen, and Terrien[10] found severe and extensive lesions of the liver in cases of infantile atrophy. These observations have not been confirmed by other men.

On the whole, therefore, it may be said that there is no convincing evidence of any constant gross or histologic changes in the intestines or liver in infantile atrophy beyond the possible absence of Paneth's granules.

The strongest argument against this theory of intestinal atrophy is furnished by clinical experience. It has been shown many times that when these infants receive a *suitable food* a progressive increase in weight occurs within a few days. Their increase in weight equals or exceeds that of the average normal infant. In atrophic cases, an average gain of seven or more ounces in a week is to be expected until such time as the infant reaches a weight that approximates the normal for its age. It is inconceivable that repair of a serious structural lesion can occur so rapidly or so completely. The only satisfactory explanation for the rapid recovery which occurs when suitable food is procured is that the condition is caused by impaired cell functions and that these functions can be rapidly restored. The nature and situation of the impaired functions have not been determined.

Rubner[11] believes that the condition is caused by impaired intestinal absorption, and states that his experiments furnished no evidence that the metabolic processes were abnormal. It would be more accurate if Rubner said that the absorptive power for cow's milk was impaired, because it has not been shown that there is any impairment of absorption when a suitable food is given.

It is quite possible that there is an intimate connection between the abnormal condition of Paneth's cells and the lessened powers of absorption. Pawlow has shown that the *succus entericus* contains a ferment which he calls enterokinase. He describes it as a "ferment of other ferments," because it acts especially on the proteolytic ferment of the pancreas and increases the latter's activity in a marked degree when certain foods are given. The activity of the amylolytic and fat-splitting ferments of the pancreas is also increased, but to a lesser degree.

These facts, taken in conjunction with the results furnished by a limited number of metabolism observations which invariably have shown diminished intestinal absorption, make it very probable that the impaired intestinal functions are of chief importance in the production of the atrophic condition of the infant.

The assumption that chronic intoxication caused infantile atrophy seemed at one time to offer a plausible explanation of the disease, but up to the present time neither the source, nor the nature, nor the actual occurrence of such an intoxication have been satisfactorily demonstrated.

In 1896, Thiemich[12] published the pathologic findings in the liver in thirty-two cases of gastroenteritis. He did not describe the cases clinically, except to say that they presented manifold appearances. He divided the cases into three classes, depending on the degree of fatty changes present. He believed the fatty changes to be due to a toxin, the source of which could not be determined histologically. Thiemich stated that he did not doubt that such changes as he found must affect the functions of the liver and hoped that the investigations which were being conducted under Czerny's direction would show a connection between the impaired liver functions and cases of infantile atrophy occurring after gastroenteritis.

In 1897 Czerny[13] stated his belief that an excess of cow's milk proteid in the diet of young infants might produce an acid intoxication. He stated that, during the process of hydrolytic decomposition of the cow's milk proteids, an excessive production of acid took place. This necessitated the withdrawal of alkalies from the tissues in order to neutralize the excess of acid, and in this way the liver functions became impaired. In support of this, he referred to the symptoms of intoxication produced in atrophic infants by quantities of cow's milk proteid, which in normal infants produced no symptoms. When the milk proteids were diminished in these cases, the symptoms subsided, but, as the food then contained too little proteid for the body needs, the infant was forced to use up its own tissues. He compared the symptoms thus produced with those which followed the operation of Eck's fistula in dogs, by means of which the portal blood is carried across into the inferior vena cava, and so does not pass through the liver. In such cases, when the dog's diet contains an excess of proteid, severe intoxication symptoms follow, and when the quantity of proteid is reduced the animals emaciate. He believed that in the cases of infants an excess of proteid, together with impaired liver functions, explained the source of intoxication.

This article of Czerny's was the first in a series of six publications which appeared from time to time in the *Jahrbüch für Kinderheilkunde* under the general title *"Zur Kenntniss der Gastroenteritis im Säuglingsalter."* Czerny's article was the first of a series, with the subtitle "Intoxication." This theory of acid intoxication and impaired liver functions furnished the basis for the above-mentioned investigations, which were carried out by men connected with Czerny's clinic. Their results appeared to corroborate Czerny's views. The second paper was written by Keller and appeared under the subtitle *"Ammoniak auscheidung."*[14] Keller found that the quantity of nitrogen excreted in the urine in the form of ammonia was enormously increased in cases of chronic gastroenteritis. He claimed that this showed either that there was more acid in the body fluids than could be neutralized by the fixed alkalies, and, therefore, the ammonia, instead of being converted into urea, was used to neutralize these acids; or else that the urea-forming functions of the liver were impaired. To test this, he administered large amounts of sodium bicarbonate to two patients. He proposed in this way to neutralize any excess of acid present in the body fluids, and if the liver functions were unimpaired he expected to find a diminution of ammonia and a corresponding increase of urea in the urine. He concluded from his results that a condition of acid intoxication was present in these cases.

The third paper in the series alluded to was that of Van den Bergh,[15] entitled, *"Einfluss von Alkalizufuhr auf die Ammoniakauscheidung."* Van den Bergh's investigations were based on the Schroeder-Munzer theory that if an excessive excretion of ammonia in the urine disappeared after the administration of large quantities of sodium bicarbonate it proved that the condition was due to acid intoxication and not to insufficiency of the urea-forming functions of the liver, because the alkaline bicarbonate of soda would not influence liver functions, but would neutralize acid if present.

Van den Bergh gave from two to five grams of bicarbonate of soda in one day to each of five infants with chronic gastroenteritis. Both the total quantity of nitrogen and the quantity of nitrogen in the form of ammonia were determined for several days preceding and following the administration of the soda. The bicarbonate of soda caused either a complete disappearance or a marked diminution in the renal ammonia. This was accepted by Van den Bergh as evidence of an acid intoxication. He omitted to estimate urea in these cases and, therefore, was unable to show that the diminution of ammonia caused a corresponding increase in urea.

The fourth paper of the series, written by Czerny, was entitled *"Respirations störungen."* In this paper Czerny called attention to a type of respiration which occurred just before death in cases of chronic gastroenteritis, and stated that it strongly resembled the type of respiration observed in animals in which an acid intoxication had been produced experimentally.

The fifth paper was written by Czerny and Keller[16] and appeared under the subtitle *"Säurebildung."* A series of experiments were made to determine the effect of variations in the diet on the production of acid within the body in cases of chronic gastroenteritis. In this, as in all their previous observations, they regarded the urinary ammonia as a measure of acid intoxication. They found that changes in the proteid and sugar content of the food produced but little effect on the excretion of urinary ammonia. Changes in the fat content, on the other hand, produced marked effects. A high percentage of fat in the food caused a marked increase in the amount of urinary ammonia. It should be stated that the percentage of fat in the food in these experiments exceeded considerably the quantity usually given to normal infants, namely, from 5.7 per cent. to 8.6 per cent. of fat. These results caused them to modify their views concerning the sources of the acid intoxication, but they continued to believe that pathologic amounts of acid were present in the body fluids of these infants. Their modified belief was that the excessive production of acid was due, in part, to the fat in the food and, in part, to the condition of the infant; i. e., the effect on the infant's metabolism produced by variations in the severity of the gastroenteritis.

The sixth and last paper in the series was by Keller and appeared under the subtitle *"Einfluss der Zufuhr von Ammoniaksalzen auf die Harnstoff auscheidung."* The purpose of this work was to determine whether or not the urea-forming function of the liver was impaired in cases of chronic gastroenteritis. Thus far, in this series of experiments, the liver functions had not been investigated. Keller administered ammonium carbonate to six infants with chronic gastroenteritis. He assumed that if the urea-forming functions of the liver were unimpaired, the carbonate of ammonia would be converted into urea and excreted in the urine. He found a marked increase in the total nitrogen and urea on the day that ammonium carbonate was given, which showed that the ammonia was absorbed. In two cases, the ammonia in the urine was lessened rather than increased, and in one case was slightly increased. Keller attached no importance to this, but concluded that the urea-forming function was unimpaired in these cases. These results were regarded as confirmatory evidence of the correctness of Czerny's theory of acid intoxication.

This work of Czerny and his associates was severely criticized by Pfaundler[17] about three years later. Pfaundler showed conclusively that some of the chemical methods employed were faulty; that many of the results were incorrectly interpreted, and that the collective results of the investigation neither proved nor disproved the presence of an acid intoxication in cases of chronic gastroenteritis. It is now known that abnormal acids (oxybutyric, diacetic, acetone) are present in the urine in cases of acid intoxication. These acids have not been found in the urine from cases of chronic gastroenteritis. In addition to this, much of the work of Czerny and his associates was based on the generally accepted theory of Hallervorden, that an excess of ammonia in the urine is always an indication of excessive acid production in the organism. Hallervorden believed that the injurious action of the acid on the tissues was averted by a combination of the acid with ammonia at the expense of the urea formation, and the excess of ammonia in the urine was regarded as a measure of the degree of acid intoxication present. This theory has been disproved.

Pfaundler denied that the type of respiration described by Czerny was characteristic of cases of acid intoxication, and said that the type of respiration described was not even peculiar to chronic gastroenteritis. He referred to the work of Van den Bergh as the weakest of Czerny's arguments in favor of acid intoxication and showed that Schroeder and Munzer's theory, on which Van den Bergh's work was based, was incorrect. It was assumed that the administration of large amounts of alkali had no effect other than to neutralize acid that might be present in the body, and in this way diminish the ammonia and increase correspondingly the urea in the urine. In three of Van den Bergh's five cases the total nitrogen in the urine was markedly diminished. It has been shown that excessive amounts of alkalies diminish the nitrogen excretion in the urine. A satisfactory explanation for this could not be given at the time Van den Bergh did his work.

[17] M. Pfaundler: Ueber Stoffwechsel Störungen bei Magen-darm-Kranken Säuglingen. Jahrb. f. Kinderheilk., vol. liv, 1901.

Pfaundler also pointed out that the diminution of ammonia in the urine corresponded to the degree of alkalinity of the urine caused by the bicarbonate of soda and explained why the estimation of ammonia in alkaline urine by Schlösing's method is inaccurate. Referring to the incorrectness of the Schroeder-Munzer theory, Pfaundler said that when fixed alkalies are administered they combine with the acid constituents of the urine and form secondary and tertiary phosphates. When ammonia gas or a solution of ammonia is added to a solution containing tertiary alkaline phosphates, no chemical reaction takes place. The chemical affinities are already satisfied, and the ammonia remains uncombined in the solution and escapes into the air in a short time. In solutions containing secondary alkaline phosphates the conditions are more favorable for the ammonia to combine. A urine that contains only secondary and tertiary alkaline phosphates, and from the presence of these reacts alkaline, can not combine to form a stable compound with ammonia.

Pfaundler thinks that the nitrogen may escape through the skin and lungs in such a case. He referred to Keller's experiment, in which he administered ammonium carbonate to test the urea-forming function of the liver, and shows that the results were not conclusive. A portion of the ammonia administered was not accounted for in the urine, and the quantity of ammonia in the feces was not determined, so there was no data to show what the absorptive power of the intestines was for ammonia, and no control observations were made on normal cases. It is not permissible to assume that the administration of an injurious substance like ammonia would produce no alterations in the metabolism.

Pfaundler referred to another source of urea which was not considered by Keller, namely, amido acids present in the diet (malz suppe) of these infants. The formation of urea from amido acids is not a function of the liver, so that other organs besides the liver must have taken part in the urea formation in these cases. In three of the observations, the increase in urea exceeded the increase in total nitrogen after giving the ammonia, showing that there was some other source for part of the urea than that of the liver alone. Pfaundler further stated that the method which was used to determine urea is not an accurate one when large quantities of amido acid and derivatives are present. He concluded that these results failed to prove that the urea-forming function of the liver was intact in such cases. He then criticized the investigations of Keller, in which he determined the quantity of ammonia in the urine in cases of chronic gastroenteritis and found Keller's figures much too high. This he attributed, in part, to the formation of ammonia in the urine on standing, and, in part, to the effect of the diet. He called attention to the extraordinary fluctuation in ammonia excretion in the course of from twenty-four to forty-eight hours without any evident explanation and with no change in symptoms. In this connection he referred to an observation made by Bendix that if the renal ammonia is a measure of acid intoxication, then very large amounts of ammonia should indicate severe cases of intoxication. Neither Bendix nor Pfaundler could detect differences in the general condition of these infants which corresponded to the amount of urinary ammonia. It was admitted by Czerny and Keller that the diet was of importance in this respect.

In addition to his criticism of these investigations, Pfaundler controlled the results, to some extent, by very carefully conducted observations on forty infants and children. These included infants whose digestions were normal and infants with chronic gastroenteritis. Some of these infants were breast-fed. He found that the urinary ammonia in the first half-year of life was much higher than at other ages. On the average, both normal and abnormal digestions were 15.88 per cent. These results were obtained in perfectly fresh specimens of urine.

With digestion normal..........	15.00 per cent.
With digestion abnormal........	16.30 per cent.
A good general condition........	13.77 per cent.
A bad general condition.........	17.10 per cent.

In a small number of cases examined in the second half-year the average was 6.28 per cent. He found little variation in the amount of urinary ammonia from day to day when the diet remained the same. Increase in the fat when artificial food was given increased the ammonia to some extent. He did not give such high percentages of fat as Keller. (Such high percentages of fat would not be tolerated for long periods by healthy infants.) Pfaundler could detect very little difference in the ammonia excretion between infants with normal and those with abnormal digestion, following alterations in the percentage of fat in the food. He showed that a physiologic hyperacidity is present in the tissues of artificially fed infants whose food contains an excessive quantity of fat. This is the condition described by Naunyn as acidosis and is not to be confounded with acid intoxication, which is necessarily an injurious condition.

Pfaundler estimated the amount of urea and amido acids and found that in the first half-year the average percentage of urea nitrogen to the total nitrogen was 55.94 per cent. in infants with normal digestion and 47.08 per cent. in infants with digestive disturbances. These figures are lower than those usually given for this age. In the second half-year, the average percentage of urea nitrogen to total nitrogen was 76.53 per cent. He found in the first half-year an average of 12.01 per cent. of the total nitrogen represented by oxyproteic acid, amido acids and, perhaps, other substances. This is much more than occurs in adult urine. The urine content of urea showed an alternating relationship between the urea, the ammonia and the amido group. In conclusion, Pfaundler referred to the work of Jacoby and others on oxidative ferments of the liver and gave his own results obtained from the examination of seventeen livers. In nine cases in which the livers appeared to be normal histologically, he found the average oxidative power to be about three times as much as that of eight cases in which the livers showed evidences of severe parenchymatous or fatty changes. He remarked that this was the more surprising, because in the cases of adults and of animals marked parenchymatous changes in the liver do not cause such impairment of function that it can be detected by metabolic investigation. He suggested the possibility that in adults there is greater reserve power or that other organs may act vicariously. In twelve of these cases, he had examined the urine during life and found that ten of them showed an alternating relationship between the quantity of urinary ammonia and the oxidative power of the liver. When the amount of urinary ammonia was above the average, the oxidative power of the liver was less than the average and *vice versa.* He admitted that these results required verification, but believed that if they could be substantiated they would have an important bearing on the nitrogen distribution in the urine and might throw light on many obscure metabolic disturbances.

Pfaundler gave the following summary: 1. The ammonia coefficient (percentage of ammonia nitrogen to total nitrogen in the urine) is decidedly higher in the urines of both normal and abnormal infants than in the urine of adults, but not so high as Keller found nor are the variations so extreme.

2. This relative increase in renal ammonia is dependent, in part, on the high fat content of the food and, perhaps, in part, on a deficient oxidative function of the liver and tissues.

3. Ammonia coefficient above the normal occurs (a) when the liver cells are diseased (extreme fatty changes;); (b) when, for any reason, the general condition is much impaired, accompanied by circulatory and respiratory disturbances. Such a condition is frequently observed before death and is not more commonly associated with digestive disturbances than with other severe disorders; (c) when artificial food contains much fat.

4. The importance of this increased ammonia excretion depends on the cause. In a and b the increase of ammonia occurs because the oxidative synthesis to urea is interfered with. In one case the liver functions are impaired; in the other case oxygen is not supplied in sufficient quantities to the tissues or else is not taken up by them. In c the ammonia accompanies acid metabolic products which prevent its synthesis to urea and this constitutes so-called alimentary acidosis.

5. The hypothesis of Czerny and Keller that chronic gastrointestinal disease in infancy causes an acid intoxication, which in turn injures the metabolic functions and is shown by increased excretion of ammonia in the urine, can not be admitted. Insofar as the increased excretion of urinary ammonia in Keller's experiments was due to relatively large quantities of fat in the food, it constitutes an acidosis, i. e., an increased acidulation of the body fluids, and is not an acid intoxication. This condition can occur in a normal organism under the same circumstances and therefore has nothing to do with the gastrointestinal disease. It can not be proved to cause injury to the organism.

In cases in which the increased excretion of ammonia is not due to large amounts of fat or to faulty composition of the food, it has the appearance of a primary retention of ammonia in the organism, therefore the opposite of an acid intoxication. This may be due to relative or to absolute insufficiency of the oxidative functions of the organism. In one case more ammonia might be produced than the liver and the urea-forming organs could oxidize, and in the other case parenchymatous changes in the liver might impair its urea-forming function.

From the evidence thus presented, it is safe to assume that infantile atrophy is caused by functional impairment. It can not be stated definitely which functions are impaired. All metabolism investigations in cases of infantile atrophy have shown a diminished power of intestinal absorption for cow's milk and for other artificial foods. The impairment of function in this case may have to do with the digestion or with the absorption of the food. I know of no metabolism investigations which show the absorptive powers of atrophic infants for breast milk. It has been demonstrated clinically many times that these infants gain in weight and in every other way with astonishing rapidity when they are fed on breast milk. It is quite possible that they may not absorb the breast milk at first any better than other food, but the organs work more economically and more benefit is derived from the quantity absorbed. Rubner's[7] metabolism observation on a normal breast-fed infant showed that the infant did not absorb well during the observation, at least so far as nitrogen was concerned, and in addition received much less milk than usual. Notwithstanding this, it did not lose in weight. The re-establishment of functions within a few days that may have been seriously impaired for months suggests something besides the mere question of digestibility of food. It is possible that human milk contains ferments that stimulate directly the functions of the digestive glands. Pawlow[18] and his associates have shown that the mechanism of digestion is much more complicated and sensitive than was supposed and that there is great variation in the quantity and quality of the digestive juices dependent on the character of the food. May it not be that the digestive glands of young infants, aside from individual variations, are less adaptable than those of older infants? The gland cells function best when stimulated by human milk. In most young infants the digestive glands can be made to adapt themselves to abnormal conditions insofar as to digest cow's milk or other artificial foods when these foods are carefully adjusted to suit the infant. These same foods when not properly adjusted cause digestive disturbances which, if long continued or of frequent occurrence, result in infantile atrophy. It is not improbable that human milk contains special ferments that stimulate the activity of the digestive glands and that when other foods are given the stimulation is less effective and easily produces a condition of abnormal digestion.

EFFECTS OF DIFFERENT FOODS ON THE ATROPHIC CONDITION.

It will be of practical value to consider the effects of different foods on this condition. It will suffice for purposes of comparison to divide the methods of feeding into three classes, viz., proprietary foods, cow's-milk mixtures, human breast milk.

Proprietary Foods.—Very little need be said about the value of proprietary foods in cases of atrophy. It is not necessary to consider their composition for purposes of comparison. All that is required in this connection is to decide whether any or all of them provide a suitable food for atrophic infants. Their usefulness in this respect can be estimated by the results obtained from their employment. In a majority of cases they prove to be unsuitable. It can not be denied that some cases of atrophy gain rapidly in weight and, to all appearances, thrive on these foods. These good results, however, are of little assistance to the physician as guides to the treatment in similar cases because they appear to follow no definite rule and subsequent attempts with the same food usually result in failure. The physician should be governed in the choice of the infant's food by the requirements of the case. A hit or miss method of feeding does not educate the physician and it is oftentimes disastrous for the patient. Almost every case of infantile atrophy that is brought to the specialist for treatment gives the history of the use of several proprietary foods. In many cases a temporary improvement follows the use of each one. The improvement is usually of short duration and then another food is tried. These histories furnish a commentary on this method of feeding.

It should be remembered that other disturbances of nutrition, for example rickets and scurvy, may occur after a prolonged use of these foods.

---

[18] J. P. Pawlow: The Work of the Digestive Glands. Translated by W. H. Thompson, London, 1902.

Cow's-Milk Mixtures.—The metabolism observations of Rubner[7] have shown that in order to utilize cow's milk an infant expends much more energy than is the case when breast milk is used. In the observations referred to the excess of energy required for the utilization of cow's milk was shown by a marked increase in the excretion of carbon dioxid and of water. There is comparatively little loss of energy due to muscular activity in young infants, and so this excessive loss is attributed to increased activity of the digestive functions. Rubner states that he believes the entire metabolism is affected in this case and not intestinal absorption alone. Rubner's metabolism investigation of a case of infantile atrophy showed that the infant was not able to digest and to absorb such large quantities of food as a normal infant. The food in this case was a modification of cow's milk with milk sugar. All the metabolism observations that have been made on atrophic infants in which some modification of cow's milk was used have shown a greatly diminished power of absorption for fats and proteids. Heubner[2] says that an atrophic infant requires more calories in its food per kilo weight than a normal infant in order to balance the extra energy lost in the intestines and absorbents during digestion. These observations coincide perfectly with the results obtained by clinical experience. It is generally considered that cases of infantile atrophy digest and gain better on cow's-milk mixtures when the percentages of fat and of proteid are low. This deficiency must be made up to some extent by increasing the carbohydrates; otherwise there is great danger that the mixture will contain too little nourishment for the infant's needs.

The fact that these infants absorb carbohydrates much better than they do fats and proteids probably explains the rapid improvement that sometimes follows the use of condensed milk and proprietary foods. In these preparations there is always a large proportion of carbohydrate material, and when milk is mixed with them it is usually so much diluted that the percentage of fat and proteid is low. By the addition of whey to milk mixtures a larger proportion of lact-albumin, compared to casein, can be obtained. This is desirable in some cases, but in my opinion most of the cases of atrophy that do badly on a cow's-milk mixture which contains a low percentage of proteid and of fat will do the same on a whey mixture. It has been shown that a relatively small quantity of proteid is required to repair tissue waste, so long as this small quantity is protected by a sufficient quantity of fat and carbohydrate. Metabolism observations seem to show that these infants possess the power of retaining proteid material to a greater degree even than average infants; and, in spite of the great loss of nitrogen in the feces, they evidently absorb enough to more than balance the tissue waste. The practical application of these facts in the use of cow's milk in infant feeding was long ago pointed out by Heubner. He thought that it was unwise to overburden the digestive organs with an excess of proteid material, and showed that more energy is required to utilize it, and that excessive amounts of it are or may become detrimental. This is especially true in infantile atrophy. Excessive amounts of cow's-milk proteid require more energy for their utilization; they are not well absorbed and resulting disturbances of function may very well interfere with the absorption and assimilation of the other ingredients of the food.

Atrophic infants cry a great deal more than do normal infants, and this is almost invariably accepted as evidence that they require more food. Further proof of supposed hunger is afforded by the fact that they do not gain in weight. The result is that when these patients are brought to the specialist for treatment he finds that they have been taking larger amounts of food at each feeding than an average infant of the same age would take. The digestive and absorptive powers of these infants are so seriously impaired that their tissues can not derive the needed amount of nourishment from the food which is supplied. When an excessive amount of food is given it defeats its purpose by impairing still more the powers of digestion and of assimilation. The results of treatment substantiate this. A majority of the cases of atrophy that recover on cow's-milk mixtures do so on relatively small quantities of a mixture weak in fat and proteid. The interval between each feeding in these cases should be shorter than for a normal infant of the same age, so that the deficiency in quantity each time is made up by an increased number of feedings. It is rarely necessary for such an interval to be less than two hours. By this means the digestive organs are not unnecessarily overtaxed and absorption is assisted. If improvement follows this method of treatment, it is necessary to keep pace with the improvement by changes in the strength or quantity of the food and by alterations of the intervals. This must be done cautiously to avoid upsets, which often follow imprudent changes in such cases.

With all these precautions, a great many cases of infantile atrophy do badly on mixtures of cow's milk. When this method of feeding succeeds the improvement is almost always slow. The progress is rarely constant. It is frequently interrupted by digestive disturbances and by periods during which there is little or no gain in weight. Under these circumstances a gain of three or four ounces each week may be regarded as encouraging. After a certain degree of improvement has occurred the progress is more rapid, but it is usually a question of several months of treatment before this condition is reached. During this time the milk mixtures have to be adjusted and readjusted many times. A limited number of emaciated infants improve at once on cow's-milk mixtures and gain rapidly in weight. Most of these cases are not, properly speaking, cases of infantile atrophy. Infantile atrophy is always associated with impairment of the digestive and absorptive functions. In the emaciated cases just mentioned the infants have been underfed, as a rule, not so much in quantity as that they have received too weak a food. In some cases, when they receive a more suitable mixture or amount of the cow's milk, they absorb it well and gain at once. These cases are cases of partial starvation and are not true cases of infantile atrophy. I have not relied solely on my own experience in making the above statements regarding cow's-milk mixtures, as any one may verify who cares to look over the literature on the subject. In my opinion, the method of feeding cases of infantile atrophy on cow's-milk mixtures is unsatisfactory in a majority of instances. The infants that do improve on cow's-milk mixtures do so because they have ultimately acquired a power to digest and to absorb this food. That is to say, the child is adapted to the food and not the food to the child.

Breast Milk.—The results obtained by feeding infants with infantile atrophy with human-breast milk have been perfectly satisfactory in my experience. The improvement in general condition and the gain in weight often begin within a few days, certainly within two weeks, and continue uninterruptedly, so far as they are dependent on digestion, as long as the breast milk is furnished in sufficient quantities. The gain in weight often exceeds that made by the wet nurse's own baby previously. Whatever function or functions have been impaired, they are evidently capable of the most rapid recovery. My experience warrants me in saying that when such an infant does not gain on the average at least an ounce a day, the fault lies with the wet nurse and not with the infant. The point which I wish to bring out clearly is that these atrophic infants are just as able to gain in weight as any normal infant when they receive a suitable food, and that breast milk is the only food that can be uniformly relied on to accomplish this result. It need hardly be emphasized that if a breast milk is of poor quality and insufficient in quantity it is no more suitable than any other poor food.

Naturally, when choosing a wet nurse, one is selected whose baby is doing well. It is not necessary that the age of your patient and the age of the wet nurse's baby should correspond. While taking breast milk, atrophic infants frequently have several more or less watery and undigested movements daily, without any evident bad results. It does not seem to interfere with the gain in weight nor with their general condition. This is peculiar to breast milk. Such dejections, if associated with other methods of feeding, would be followed by bad symptoms. It can not be denied that there are many objections to the use of a wet nurse. The serious ones, which refer to contracting diseases by the infant, can be avoided. The others must be tolerated to some extent. It must be remembered that in these cases the family of the patient are discouraged and worn out with the care of the infant, and when they see almost immediate and marked improvement they quickly become reconciled to inconveniences and are willing to put sentiment aside. Wet nurses can be controlled up to a certain point, and in this connection it is always a fatal mistake to encourage a belief by the wet nurse that she is indispensable. If she is not satisfactory, another can be procured. It is a fallacy to suppose that one woman's milk is any more suitable for a given infant than another woman's, provided both milks are good, that the quantity is sufficient, and that no mechanical hindrance exists in the one case and not in the other. If the wet nurse is made to understand that the place is hers only so long as the baby does well and she is satisfactory, it will make a difference in her behavior. I have rarely found it necessary to try more than two wet nurses in a given case, but now that I feel so certain that good results will follow this method of feeding in cases of atrophy, I should persevere until a suitable wet nurse was found, no matter how many I tried. The difficulty in making infants accustomed to the bottle take the breast is rarely serious. Persistently withholding other food for some hours will overcome their resistance. I have often found it necessary to allow the wet nurse to retain the charge of her own baby. In such cases the wet nurse's baby was fed on a mixture of cow's milk. It can not be denied that one would rather not be burdened with the wet nurse's baby, but, on the other hand, the care of her baby oftentimes reconciles her to the position and helps to occupy her time. The possibility or probability that she will nurse her own baby can be avoided without much trouble.

In my practice, when cases of atrophy are brought to me for treatment, I make it a point to express my views to the parents on the relative values of different foods. They almost always object at first to the employment of a wet nurse. Out of deference to their feeling and because it is always possible that whoever has had charge of the feeding previously has not made use of mixtures appropriate for such cases, I try mixtures of cow's milk for from two to three weeks and note the results. If the improvement is not satisfactory I recommend a wet nurse. I should omit the preliminary trial if the infant's general condition did not warrant it. Thus far I have never had occasion to regret employing a wet nurse. In many cases even a few weeks of the breast milk will produce such improvement in the weight, general condition and digestive powers of the infant that it will be able to adapt itself to cow's-milk mixtures if for any reason it becomes necessary or desirable to change.

THE ELIMINATION OF THE MOSQUITO.*

ALVAH H. DOTY, M.D.
NEW YORK CITY.

I am quite sure that the members of the American Medical Association are familiar with the general literature regarding mosquitoes, and that a detailed account of the different varieties of these insects, their anatomy, method of development and the physiologic reason why they transmit disease is unnecessary. I have chosen, therefore, to present some practical facts which have a direct bearing on the work of exterminating the mosquito.

A decided and very satisfactory change has taken place in the attitude of the public toward this subject during the past three or four years. At first, efforts to exterminate the mosquito in this country were looked on mainly from a humorous point of view, and but little co-operation was extended by the laity. The public, however, has learned that the object of this work is not only to prevent the annoyance which the bite of this insect inflicts, but also to prevent the transmission of the disease, inasmuch as it has been proved that yellow fever is transmitted by the variety of mosquito known as the stegomyia, and malarial fever by the anopheles, and that so far as we know at the present time this is the only means by which these diseases are propagated.

In the extermination of the mosquito, it is imperative that we should be familiar with certain habits or conditions of this insect, otherwise our efforts are not apt to be attended with success. We must know, first of all, that mosquitoes propagate only in water. The importance of this fact is that it gives definite information regarding the situation of breeding places. We know that the eggs deposited on the surface of the water develop into the larvæ, commonly known as the "wigglers," then into the very transient stage of the pupæ, which in appearance may be regarded as a change in the shape of the larvæ, and that these are very soon transformed into the winged insects, and that from the deposit of the eggs to the development of the winged insect only from twelve to twenty-five days elapse. The latter period, as a rule, is required for the development of the anopheles or malarial mosquito. So far as my own investigations show, the propagation of the mosquito is, as a rule, most active in stagnant or offensive waters, or in that which contains considerable organic matter. Two instances have recently come under my observation where broken sewer pipes discharged into ground depressions, causing collections of offensive water. In the immediate vicinity of these were pools of water which were not contaminated; i. e., collections of rain water and not of offensive fluid. In both instances it was found that the contaminated water soon became exceedingly rich in mosquito larvæ, whereas in the other pools, within two or three hundred feet distant, which contained comparatively clear water, there were very few, if any, larvæ found.

---

* This paper was prepared for the Section on Hygiene and Sanitary Science, but was not read, owing to the absence of the author.

Experiments made at the New York Quarantine Station have practically corroborated this. In these experiments large superficial wooden tanks were employed, in which different kinds of water were placed; i. e., rain water, hydrant water, water in which decomposed meat and fish had been placed and water containing other offensive material. These tanks were exposed, side by side, in a place infested with mosquitoes. In all the tests, it was shown that the deposit of mosquito eggs was always greater in the tanks containing the offensive water. Experiments on a smaller scale were also made. Exposed pails and glasses containing the different kinds of water already referred to were employed and the same results were noticed, viz., the deposit of eggs was much greater in offensive water. These experiments were repeated many times with the same result and fully confirmed the conditions, which I have found in mosquito-breeding districts. The experiments to which I have just referred were made with the culex, which is the commonest type of mosquito. There is, however, a variety of the culex known as the *Culex solicitans*, the striped-legged, Atlantic coast or salt marsh mosquito, which may be excepted from the above, inasmuch as it breeds in salt water or in salt or brackish marshes. Furthermore, the malarial mosquito, known as the anopheles, while it may be found breeding in offensive water, prefers small pools of water which are not so contaminated and which may be found in excavations containing surface water frequently having a green scum on the surface. I have found the anopheles larvæ in water contained in small ground depressions along the edge of swamps, also in unused receptacles which are found about houses. Occasionally the anopheles larvæ may be found in the same breeding pool with the culex; this, however, is not common. In a general way, it may be said that mosquitoes will breed in almost any receptacle and in the most unusual and unsuspected places, commonly in rain-water barrels, cisterns, cesspools, tin cans and other metal, glass and wooden receptacles, roof leaders, crotches of trees, etc. It is very necessary that physicians should be familiar with this fact.

It is a common belief that mosquitoes will not breed in salt marshes. My experiments show that in captivferred to the fact that a variety of the culex, known as the *Culex solicitans*, or the Atlantic coast, striped-legged or salt-water mosquito, breeds in salt water or in salt marshes. My experiments show that in captivity the *Culex solicitans* will sometimes deposit their eggs on fresh water contained in glass jars; whether or not they will do this if they are free has not yet been fully decided. It is probable that along the Atlantic coast the salt marshes in many places furnish fully 80 per cent. of the mosquitoes in these sections. Dr. John B. Smith, State Entomologist of New Jersey, who has carefully investigated this variety of mosquito, states that it will deposit its eggs on the soft earth, in salt marshes along the sea coast, and that these eggs will remain intact for months until the swamps overflow and there is sufficient water to develop them into larvæ and subsequently into the winged insects. My experiments have partially confirmed this. I have confined the Atlantic coast or striped-legged mosquitoes in glass jars, in which was placed soft earth taken from salt marshes along the coast, and it was soon found that the eggs were deposited on this material. When salt water was added to this, after the eggs had been laid a number of days, the larvæ very promptly appeared. No proof, however, has ever been produced to show that the larvæ can be developed from these eggs without the presence of water. If the *Culex solicitans* be confined in water to which various amounts of salt have been added or in jars containing sea water, a deposit of eggs on the surface will soon be noticed; however, I have been unable to secure this result with any but the Atlantic coast mosquito.

A general impression exists that the life of the mosquito is very short, probably a few days only. While it is true that the mosquito is not a resistant insect and easily succumbs to all sorts of influences, it is a fact that it lives indefinitely. In the hibernating stage it is known that it may live from the fall to the following spring, and during the warm weather, or in its active stage, it may live a number of weeks. It is practically impossible to arrive at any definite conclusion regarding the life cycle of the mosquito, inasmuch as experiments do not furnish satisfactory evidence, for the reason that they can not be carried out under the same conditions that naturally exist. In other words, mosquitoes may die from captivity alone, or when they are unable to select the character of food which they require. It is safe to assume, however, that if they will live a certain period in captivity, they will live equally long when they are free to go and come as they please. There have been many investigations made and published on this point, and experiments have shown that in captivity mosquitoes will live for a number of weeks. I have kept them in wire cages containing nothing but sugar water for almost two months; furthermore, mosquitoes may be kept for a long period in captivity without food or water, provided sufficient air be present. Aside from the interest in securing definite knowledge in this direction, the length of time which mosquitoes may live in captivity has an important practical bearing, as it has been claimed that yellow fever may be transmitted from one place to another through the agency of the stegomyia, or yellow fever mosquito, confined in baggage, etc. In order to secure so far as possible definite information regarding this part of the subject, I carried out the following experiments: A number of boxes which could be compared to trunks, also canvas bags, such as sailors use to contain their clothing, and other receptacles were filled with clothing, blankets, bedding, etc. Mosquitoes were collected from a horse stationed in a thickly infested mosquito district. This was done by placing glass test tubes over the mosquitoes. When a sufficient number were secured the openings of the tubes were filled with light cotton plugs. The tubes were then introduced into the receptacles already described, the cotton plugs removed and the tubes gradually withdrawn and shaken sufficiently to drive out the mosquitoes. This method was employed in order to prevent any possible injury to the insect. In each experiment a record was kept of the number of mosquitoes in the different receptacles, and, although many experiments were made, it was found that in no instance did the mosquitoes in any receptacle live longer than thirty hours. I believe, therefore, that the treatment of baggage coming from yellow fever ports is unnecessary, provided the period of transit exceeds two days.

Considerable discussion has taken place among those who have investigated the mosquito regarding the origin of the first crop of these insects, which appear in the spring or summer of each year. As I have already stated, Dr. John B. Smith claims that the egg of the *Culex solicitans,* or striped-legged or Atlantic coast mosquito may be deposited on the moist earth, in brackish or salt-water swamps, and that in this situation, he believes, they will remain dormant or hibernate until the following spring, when an overflow of water takes place and the eggs become active and are developed into larvæ and subsequently into the winged insects. It has also been shown that larvæ will hibernate and that during the winter they may be found in ice and after being thawed out become active. The latter phenomenon has come under my notice, but I have seen no instance in which larvæ after being frozen and thawed out have developed into winged insects. This may occur, but I am sure that it is uncommon. Although the eggs of the *Culex solicitans,* Atlantic coast or striped-legged mosquitoes, may hibernate during the winter, and be the origin of the first crop of this variety of the mosquito in the spring or summer, I am satisfied from my own experiments that the first crop of mosquitoes which come to us each year, particularly in inland towns, or about fresh water supplies, is due to the hibernation of the winged insect. It is common experience with all who live in mosquito-infested districts frequently to find these insects in midwinter, particularly in overheated rooms, etc. It is evident that when the cold weather approaches the mosquito instinctively seeks some protected place, such as crevices in the interior of tree stumps, cellars, barns, interior of houses, etc., and, while there are probably but comparatively few which do not succumb to the cold weather, sufficient survive to perpetuate the species during the following year.

Another very much disputed point regarding the mosquito is whether or not they go far from their breeding places. While there is indisputable evidence that mosquitoes at times are found far from home, there is also the best evidence that they do not go willingly. One of the most satisfactory instances that I know of, which proves that they are found some distance from their breeding place is that furnished by the New York harbor pilots, whose boats are frequently anchored along the Jersey coast, three or four miles from land—occasionally they become suddenly infested with mosquitoes. The pilots are unanimous in their statement that when this occurs there is always a breeze from the shore. While indisputable evidence has been presented to show that mosquitoes go far from home on land, as well as at sea, there is good reason to believe that this does not commonly occur. It is the opinion of all who have carefully studied this insect that they do not willingly go far away, and I believe that we are justified in assuming that if a section of country be infested with mosquitoes a breeding place exists in the immediate vicinity. I speak emphatically in this matter, as many times after it has been positively stated that mosquitoes must have come a long distance, it has been found that breeding places existed in the neighborhood, and there is no doubt that the difference of opinion which existed on this subject is largely due to the fact that local breeding places are frequently overlooked. When it is remembered that the female mosquito will lay three or four hundred eggs at one time, and that it only requires from twelve to twenty-five days for these eggs to develop into the full-grown winged insect, it will be better understood how a small receptacle will breed a large number of mosquitoes. Therefore, before hunting for the breeding places of mosquitoes at some distance from home, we should first examine every detail of our own premises to ascertain if receptacles for the propagation of this insect can not be found.

These breeding places are often discovered in the most unsuspected locations. In connection with this and as an item of interest, I will refer to an investigation made two or three years ago. My attention was called to a number of cases of malarial fever occurring in two or three houses adjoining each other. Anopheles were found in the bedrooms of these patients during the evening. In close proximity to these houses were found numerous pools of water, and, although each one was examined with great care, no anopheles larvæ were found. The most careful inspection was made of every cistern, rain-water barrel, etc., in the neighborhood with the same result. This lent some color to the belief that the mosquito in this instance might have come from a distance. Further investigation was made, however, and in the garden of a house in the rear of those containing the cases of malarial fever, and which had been vacated for some time, was found an old cake pan almost entirely covered by long grass, and in this was found a large number of anopheles larvæ. An ordinary inspection would not have discovered this receptacle.

As a résumé of what we know at the present time, it may be said:

First, mosquitoes do not propagate without water, and, as a rule, so far as the culex is concerned, the more offensive the water, the greater the propagation. Although the anopheles or malarial mosquito will propagate in offensive water, sewerage, etc., they are more apt to be found in small collections of water, about fresh water swamps or in small receptacles about the house. In large ponds or pools of fresh water, particularly those which contain small fish, which prey on the larvæ, mosquitoes of any variety are not usually propagated, but the little pockets of water along the edges of these ponds or in other places frequently act as breeding places. We also know that a variety of mosquito known as the *Culex solicitans,* or the striped-legged, Atlantic coast or salt marsh mosquito, breeds in salt water or in salt marshes. Mosquitoes breed in cisterns, rain-water barrels and cesspools in enormous number; other receptacles about the premises, no matter how small or where they are situated, may also act as breeding places. It is about our own homes, therefore, that the examination should first be made to ascertain where the propagation of this insect is carried on.

Second, the life of the mosquito is not confined to a few days, but under various circumstances may extend over a period of weeks or months.

Third, the first crop of mosquitoes which appears in the early summer of each year, particularly in inland towns, is principally due to the deposit of eggs which have hibernated during the winter months. These, of course, are comparatively few in number, but are sufficient for the purpose above referred to. The variety of the mosquito known as the *Culex solicitans* is probably largely perpetuated by the hibernation of eggs, which are deposited in the soft earth, in salt marshes along the sea coast, and remain dormant during the winter; when the warm weather returns and the marshes are overflowed with water, these eggs become active and develop into larvæ; subsequently into winged insects.

Fourth, although there is conclusive evidence that mosquitoes are sometimes carried long distances from home, they do not willingly go far from their breeding places, and it may be assumed that if a section is infected with mosquitoes breeding places exist in the immediate vicinity. It is probable that an exception may be made in the case of the *Culex solicitans*, or salt-water mosquito, which appear to go further from home than other varieties of the culex or the anopheles. There is good reason to believe, however, that they do not breed away from the salt marshes or in collections of fresh water.

Efforts to prevent the propagation of the mosquito consist in abolishing or removing receptacles which contain water. This applies to both large and small ground depressions, swamps, etc., and to portable and stationary receptacles about buildings. The scientific, practical and radical method of removing water in ground depressions is by drainage or filling in, and the use of petroleum oil in these instances can not be regarded as a substitute for this purpose and should only be used as a temporary measure. In mosquito-infested districts our first action should be to remove, so far as possible, from dwelling houses and other buildings, all sorts of metal, glass and wooden receptacles for water. Cisterns and rain-water barrels should be supplied with tight-fitting covers; by having the center of these covers constructed of wire netting sufficient air is admitted. Roof leaders should be kept properly graded; otherwise parts of them may act as breeding places for the mosquito. If ground depressions either about the premises or in the neighborhood can not be drained or filled in, petroleum oil may be used as a temporary measure. The crude petroleum is probably superior to the refined oil and should be used in the proportion of one pint of oil to a water surface of about twenty feet in diameter —even a less amount of oil may be effective. This procedure should be repeated every two weeks. The method by which the oil destroys the larvæ or wigglers is probably not by a toxic effect, but by a mechanical one. The larvæ must come to the surface of the water for air at least every two minutes. If watched carefully it will be seen that the culex, or common variety, approach the surface of the water at right angles, with the tail uppermost, the air being taken in at this end, which is extended sufficiently above the surface. The anopheles larvæ may be distinguished from the culex at this stage, inasmuch as they do not lie at right angles to the surface of the water, but parallel to it, and receive the air by projecting the head above the water instead of the tail. It is probable that the oil thrown over the surface plugs up the delicate respiratory apparatus of the larvæ and practically suffocates them. This is largely corroborated by experiments. If a small amount of petroleum oil is thrown over the surface of the water in a glass jar containing larvæ, the latter will succumb in from ten to twenty minutes; toxic agents do not kill them with such rapidity, as careful investigation has proved. The odor of petroleum oil is either very unpleasant or injurious to the winged insect. It has frequently been noticed when petroleum has been used in swamps in large quantities that the number of mosquitoes abruptly diminishes.

In treating large bodies of water with petroleum, the ordinary garden sprinkling pot is a good and practical method of distributing it. Experiments made with permanganate of potassium, bichlorid of mercury, sulphate of copper, carbolic acid, etc., have shown that these agents are greatly inferior to petroleum for this purpose. Their action is slow, and the mosquito larvæ live in comparatively strong solutions. For instance, larvæ have remained active from one to three days in a 1/1500 solution of bichlorid of mercury. Even comparatively strong solutions of carbolic acid or permanganate of potassium do not destroy them for some time. In some very exhaustive experiments made with sulphate of copper and lime for the destruction of mosquito larvæ,[1] I found that these agents did not destroy the mosquito by a toxic effect, but slowly by clarifying the water and precipitating the organic matter which it contained, thereby removing the nourishment from the larvæ. Furthermore, it must be remembered that pools of water throughout the country may be used for drinking purposes, particularly by animals, and that the use of such agents as bichlorid of mercury, carbolic acid, etc., are, therefore, unsafe. On the other hand, the petroleum oil is cheap, practically harmless and destroys the larvæ at once, and so far as we know at the present time is superior to anything else for this purpose, provided proper drainage or filling in can not be effected.

All varieties of mosquitoes are most active after sundown. This we know not only from the annoyance which they cause us, but from the indisputable testimony presented by medical experiments with the malarial and yellow fever variety. During the day, when the mosquitoes are generally inactive, they select for their abiding place the high grass and underbrush. Therefore, this material should be removed if present about the premises in mosquito-infected districts.

The points to which I have referred in this paper constitute the bulk of what is at present really known regarding the habits of the mosquito and the means of exterminating them. Many investigations, however, are now in progress in this country, and there is good reason to believe that much valuable information will be added to our knowledge during the next year.

ANKYLOSTOMIASIS OR UNCINARIASIS.[*]

T. M. RUSSELL LEONARD, L.R.C.P., L.R.C.S. (ED.)
GRENADA, BRITISH WEST INDIES.

This disease, an endemic anemia caused by the parasite. *Ankylostoma duodenale* or *Uncinaria duodenalis* and *Uncinaria americana* (Stiles), is a dangerous one both to the individual and to the community in general, leading as it does in individual cases to degeneration of important organs, resulting probably in death and to widespread infection and deterioration among the community in general.

The parasite is now too well known to need a full description; in Grenada, B. W. I., the large majority of cases show the old world parasite, viz., *A. duodenale* but in many many cases I have come across the variety described and named by Stiles, *Ankylostoma* or *Uncinaria americana,* the new world variety. The chief differences between these two species lie in the size and the armature of the mouth; the *Ankylostoma duodenale* being larger with a heavily armed mouth, viz., two pairs of hook-like ventral teeth and one pair of dorsal, the *Uncinaria americana* being smaller with 2 pairs of ventral plates or lips and one dorsal pair (Stiles). Microscopically the worms appear as short threads white or gray in color, according to the contents of the genital organs, usually I have found that the white are males and the gray colored ones females with ova; I have only occasionally seen them blood red.

---

DEVELOPMENT.

The ovum develop in earth under favorable conditions of humidity and temperature and shade. I have found that a certain proportion of water is necessary, in undiluted feces the larvæ appear but soon die; in feces diluted with much water, in a few cases of mine the larvæ appeared; but did not live, but in the majority the ova did not develop. The ova developed at the ordinary temperature in this island, viz., 80 to 90 F., but the larvæ are killed and the ova prevented from developing when placed in ice. Direct exposure to the sun light killed the larvæ when these had developed and also prevented the ova from developing so that a certain amount of shade is required for the development of the larvæ from the ova. Each ovum only produces a single larva and this never takes place within the host but outside so that an increase of adult worms in any particular case is impossible without reinfection from without; this point is therefore of great importance both in the treatment and in the prevention of this disease.

MODES OF INFECTION.

Two methods of infection are possible: 1. By the ingestion of the larvæ in the food or water; 2, by penetration through the skin and subsequent migration to the intestine where the embryos mature into the adult worms.

In Grenada the class found to be chiefly affected with the disease are the laborers and agriculturists, consisting chiefly of negroes, East Indians and poor whites. The huts occupied by them are small, usually raised a few feet off the ground in most cases, entirely surrounded with vegetation almost up to the walls, in this island being chiefly bananas and cocoa and other trees planted to protect the growing cocoa. Sanitation is unknown among them and latrines never used, the feces being deposited on the earth among the trees so that in time the soil, around these huts and also in the fields where they work, becomes heavily infected. During the rains, the mobile larvæ also ova are washed down into the pools, shallow wells and streams and as most of the villages depend on such for their drinking water, it can be readily understood that infection in this manner, viz., by ingestion, can take place; helped to a very great extent by the dirty habits of the people such as eating with soil-stained hands, improperly washed vegetables and fruit and as above stated drinking water infected with the larvæ and containing a large quantity of earthy matter in suspension. I am of opinion that in this island at any rate this method of infection takes place as the drinking water contains to my knowledge both the living larvæ and earthy matter in suspension, so that although many observers have remarked and I have proved to myself that the embryos die on drying and that the earth taken in must be moist yet in the above condition we have both earth and moisture. True geophagy is not practised to any extent in this island, chiefly among children, so that a few cases may be set down as due to this method of infection.

The second method of infection, viz., penetration of the skin by the larvæ, is without any doubt the true one as proved by the experiments of Looss and others. In every case treated by me I have always elicited the fact that the patient has suffered from a form of dermatitis known in this island as "chauffie" or "grounditch" prior to his anemia, the period ranging from 3 months to a year or two, and in advanced cases, they have had attacks every year especially during the rains. I have had 10 cases of this dermatitis under treatment in the hospital and the following were the chief characteristics; in cases of recent infection, scattered vesicles were seen, many of which broke down, leaving small ulcers, usually affecting the lateral side of the feet and the urb of the toes; in older cases the ulceration was more extensive, deep cup shaped ulcers being seen on the dorsum and lateral parts of the foot and between the toes. Some of these cases resisted treatment for some time, although in the early cases they healed quickly. These cases remained under treatment and in about 3 to 6 months from the date of the first appearance of this dermatitis they complained of uneasiness in the epigastrium, in some cases actual pain and other dyspeptic symptoms and on my examining the feces later I found the characteristic ova, thus showing that this dermatitis known here as "chauffie" is caused by the penetration of the skin by these larvæ. This skin infection is wide spread in the island, especially on the estates and among the villages, and nearly every adult laborer has had it and also the children who are allowed to roll about and play in the earth around the huts.

The disease chiefly affects the country and very few cases are seen in the larger towns and this fact is easily explained as follows: No sanitation in the villages, feces deposited on the earth among the bananas and cocoa trees; the ideal temperature, shade, humidity and decaying matter being afforded by these groves for the development of the ova and the poverty and filthy habits of the class as a whole, necessitating walking barefooted, infecting himself and then carrying it to his hut and infecting the children in turn. With regard to immunity from this disease, there is none; all classes may become infected but the poorer classes are more liable not only from the nature of their work, poverty, but also to the inadequate diet both in quality and quantity.

SYMPTOMATOLOGY.

Within the past year, April, 1904, to April, 1905, I have had 215 cases under my treatment and observation at the Colony Hospital, these cases were simply admitted as they applied and a large number also suffered from other complications. I found that uncinariasis could be divided into two distinct classes, (a) acute, and (b) chronic, the acute class being further subdivided into (1) mild cases and (2) moderate. On a microscopic examination of the feces the ova can be readily detected but the number present in the field is no guide to the extent of the infection, in many cases, although if large numbers are seen it is probable there are a large number of parasites but the reverse is no necessarily correct. The mere presence of this par does not constitute the disease and these early cases are only of importance from their being a source of danger to others and to the district or village in which they reside.

Mild Cases.—Pain or uneasiness in the epigastrium often relieved by but usually increased by the ingestion of food. Appetite lost but in many cases ravenous. Frontal headache, dizziness and palpitation, breathlessness on exertion, and indisposition to do any work, either physical or mental. In these cases anemia was not marked and pallor was only slight, being yellowish in whites and muddy in the colored races.

Moderate Cases.—In these cases all the above symptoms were pronounced, pallor is more marked and the anemia prominent. The mucous membranes and conjunctivæ pale, skin dry, appetite in the majority of cases lost, nausea and vomiting present in many cases, pain in the epigastrium. Headache is very severe and continued, referred chiefly to the frontal region, often temporal, vertigo and extreme tinnitus present. Palpitation is severe and breathlessness ensued on the slightest exertion. Great languor and lassitude is complained of, and fever of an irregular, intermittent type is present with pains in the joints.

Chronic or Very Advanced Cases.—Here the anemia is intense and pallor very extreme, the patient having an icteric tinge of the sclera. Edema of the feet and ankles is present with general anasarca in the majority of cases and in 8 cases under treatment ascites was present. The digestive symptoms have changed, either becoming more pronounced, with vomiting on ingestion of food, or in many cases they disappear altogether. Precordial pain and pain in the chest is complained of, palpitation is severe and dyspnea comes on with the slightest exertion, the pulse is weak and compressible and pulsation of the large veins of the neck is noticed. Vertigo and tinnitus is extreme, this latter symptom often causing sleeplessness. Dimness of sight is complained of and in many cases the pupils are noticed to be dilated. The urine is normal in quantity, usually pale in color and in only 3 cases was albumin present. On auscultation bruits are heard over the veins and there is a well marked murmur on the valve areas and the heart itself is often dilated with the apex beat depressed. The muscular system is weak although the muscles appear plump and well nourished and the patient is absolutely incapacitated from any kind of work. The patient is listless and apathetic and the temperature is often raised but in the majority of cases it is subnormal.

Digestive System: Stomatitis.—In two cases only have I seen a stomatitis affecting the tongue and mucous membrane of the mouth and both these cases were in the advanced stages. I do not attach any importance to it as I have not seen it present in other cases. Pyorrhea alveolaris is very common in this island among the laboring class, also caries of the teeth and may be noticed in all the cases of the disease, but I do not see any connection between them.

Tongue.—In the acute and chronic cases, the tongue is very pale, almost white in color, usually coated but often red and raw looking and denuded of epithelium. I have remarked a peculiar pigmentation seen in every case except the poor whites. It consists of a black or blue black pigmentation, in minute spots either singly or in patches usually on the tip and sides of the tongue; it is not seen, as I mention above, in cases in whites but only in the pigmented races, negroes and East Indians; I am of opinion that there is some connection between this pigmentation and the disease but so far I have not been able to establish it. The digestive symptoms are very similar to those due to dyspepsia, and often in the mild cases are simply treated as such, the feces not being examined with the result that the case steadily progresses instead of improving. Appetite is variable, being lost in many cases but ravenous in others; pain or uneasiness in the epigastrium is a well marked symptom and is likened by the patient to the sensation of having a stone in the stomach; this symptom is usually increased by the food taken by the laboring class here which is of poor quality and very coarse and bulky, quantity instead of quality being preferred. Flatulence and palpitation is very common and the bowels are usually constipated, only in the very advanced cases have I seen diarrhea.

Circulatory System.—On inspection, the apex beat is found to be pronounced, especially if the patient is made to walk a little and is usually displaced downward and to the left, but in many of the chronic cases it is feeble. On percussion, the cardiac area is found to be enlarged in the second class of cases and in the chronic cases dilatation is present. On auscultation bruits are heard, very marked in the third left space and in 8 cases under my treatment they were practically organic, fatty degeneration and dilatation having occurred. (Two of these cases died in hospital and enabled me to make an autopsy.) Precordial pain and pain in the chest, palpitation and dyspnea are present and are very distressing symptoms in chronic cases. Vertigo and tinnitius aurium are also other well marked symptoms especially in the later stages and are no doubt adjuncts in causing the inability of the patient to get about and in producing the sleeplessness complained of in many cases.

Nervous System.—Symptoms pointing to this system are languor and lassitude, mental apathy, insomnia and the severe and continued headache, usually frontal often temporal and sometimes the pain is referred to the whole head. Numbness of the feet and formication are complained of as well.

Integumentary System.—The skin is harsh and dry, and in the chronic cases general pruritus is often a constant and very annoying symptom, atrophy present in chronic cases.

Feces.—In all the above cases I have not seen any blood in the stools, but in 6 cases I have noticed blood stained mucus; but it is not a constant symptom. I have mentioned that constipation is usually complained of but diarrhea may occur. Miscroscopically the ova are readily seen, in conjunction with those of *Ascaris lumbricoides, Tricocephalus dispar* but I have also found them in conjunction with those of *Oxyuris vermicularis* and in 20 cases *Rhabdonema intestinalis* was present.

Blood Examination.—On a microscopic examination, the point that is noticed is an increase of the eosinophiles, but on making a count there is no marked leucocytosis, the percentage of hemoglobin varied but there was a slow but steady decrease as the disease advances, but it was also noticeable that after treatment and when the patient began to improve the red corpuscles increased but the per cent. of hemoglobin often fell before it began to rise.

The following table shows the percentage obtained by me from blood counts in 20 cases: Eosinophiles, 18; polymorphonuclear, 55; large lymphocytes, 8; small lymphocytes, 17; other cells, 2; total, 100. Hemoglobin varied from 8 to 40 per cent.

Diagnosis.—The diagnosis of the disease depends not so much on the symptoms, which, although they may be well known, are very often mistaken for those of dyspeptic troubles in the mild cases and of heart disease in the advanced cases, but on the discovery of the ova in the feces. The ova are very characteristic and can not be mistaken for those of any other parasite as they are unstained by bile, while those of the other parasites are usually stained yellow. The ova of the *Oxyuris vermicularis* may be mistaken by beginners for that of *Ankylostoma*, but a little practice enables them to be easily distinguished. The *Ankylostomum* ova are perfectly clear and chitinous, shelled with a granular grayish vitellum, usually segmented into four, sometimes six or eight parts; those of *Oxyuris* are smaller and the vitellum is not segmented but fills up the entire shell. In many cases the temperature is of an irregular intermittent or remittent type, patients complaining that the fever comes on every night or morning, and this fever often causes the disease to be mistaken for malaria. A microscopic examination of the blood soon clears this point, although malaria is very often, especially in certain districts of this island, a complication of the disease, and when the case is treated as one of malaria without an examination of the feces having been made, the practitioner is surprised to find that quinin has, seemingly, no effect on the temperature. (I had a case of this nature sent into hospital—vide report on case attached.)

MORBID ANATOMY.

The following data are taken from four autopsies made by me at the hospital on bodies of patients who died from advanced uncinariasis. One died suddenly (forty-eight hours) on the second day after admission (this case I have described separately, with a complete history).

General Condition.—The bodies appeared plump and well nourished, the skin was harsh and dry, of a dirty, muddy color, edema of the feet and ankles with ascites was present, and there was serous effusion into the various cavities, viz., pericardium, pleuræ and ventricles of the brain; subcutaneous fat was abundant and yellow in color.

Heart.—The heart was found to be enlarged, fatty degeneration and dilatation being present with incompetence of the valves; the heart walls were thin and flabby, and patches of atheroma were present in the aorta. The cavities were found filled with soft dark clots.

Lungs.—The lungs appeared normal, although pale in color, but in one case advanced pulmonary tuberculosis was present and was no doubt the cause of death. Pleural cavities contained about a pint of clear yellowish fluid.

Spleen.—This organ appeared normal in 2 cases, but in the others was enlarged and fibrous, probably due to malaria, as both cases came from a very malarious district.

Liver.—This was pale slightly enlarged in all the cases; fatty degeneration was present and the tissue very friable.

Kidneys.—In one case the kidneys were small, pale, capsule adherent (chronic interstitial nephritis), but in the others they appeared normal, although pale in hue.

Stomach.—This organ showed signs of chronic catarrh, in 2 cases dilatation was present, but I did not find any uncinaria in the cavity of the organ.

Intestines.—The parasite was found in large numbers, were chiefly in the upper part of the jejunum, but also in the duodenum. The parasites were lying free in the lumen of the bowel, but a great many were attached to the intestinal wall. There was a large quantity of mucus present in the intestine, in which the worms were lying embedded. The mucous membrane should show minute hemorrhagic spots, as well as pigmented spots. In one case the wall itself was very thin. There was no blood in the intestines.

Brain.—The brain showed anemia with effusion into the ventricles of a pale yellowish fluid.

The above four cases were the only ones that died and enabled me to make an autopsy. The majority of the cases made rapid and uneventful recoveries, but a few of the very advanced cases were slow and remained in hospital over three months before being discharged.

PIGMENTATION OF TONGUE AND ITS PROBABLE CAUSATION.

In every case of ankylostomiasis under my treatment, with the exception of the poor whites who are of European parentage, the pigmentation of the tongue is seen. It consists of minute black, blue-black or brown spots, usually on the lip and sides of the tongue; sometimes the pigmentation is seen in larger areas. The colored races in this island, viz., the negro, East Indian and their descendants, show this pigmentation in every case of uncinariasis and it is especially marked in the chronic cases.

Pigmentation of the skin and mucous membranes may be derived either from the blood or bile or from external agents. In these spots the pigment is deposited chiefly in the mucosa of the papillæ in its lower layers, but also in the upper layers. There is no doubt that disturbed innervation plays a part in producing this result, as is seen in the bronzing of the skin in Addison's disease, which is probably due to inflammation of the abdominal sympathetic. The pigment melanin closely resembles hematin, one of the constituents of the hemoglobin, in its composition, hence we can conclude that it is derived from that source. Its presence is usually associated with two very opposite conditions of nutrition, being sometimes an accompaniment of tissue degeneration and at others of active trophic changes. It is well known that the chlorophyl of plants and the hemoglobin of the blood are intimately associated with respiratory changes. In the majority of cases where pigment is found some concomitant blood change is also present, as, for instance, in malaria, pigment is formed from the destruction of the red corpuscles and deposited in various organs of the body, and without doubt deposition of pigment is very probably under the control of the sympathetic system.

In uncinariasis we have a toxin produced by the parasite and which is the true cause of the profound anemia, blood and nervous changes. Here, therefore, we have both the necessary factors for the production of pigmentation, not only on the tongue and mucous membranes, but elsewhere, viz., (1) blood changes in which the hemoglobin of the red corpuscles is broken and disintegrated, as shown in the reduction of the hemoglobin percentage as the case advances, and (2) disturbance of the nervous system by the same toxin which affects all centers sympathetic included, as evidenced by the symptoms.

Dr. Laycock has observed that pigmentation may be regarded as having reference to the excretion of carbon after it has served its purpose in the tissues, and hence, pathologically, pigmentation may be taken to be expression of (1) imperfect oxidation of the carbon so that it is not eliminated as carbonic acid from the body, (2) excessive production of carbon from highly carbonaceous food, (3) pigment resulting from the disintegration of the hemoglobin of the red cells. In uncinariasis all three of these factors are present, produced by the toxin excreted by the parasites, (1) diminished oxygenating power of the blood from destruction of the blood cells so that carbon waste is not got rid of, (2) presence of hematin from disintegration of the hemoglobin, and in this island (3) we have the third factor, viz., excess of carbonaceous food, as the laborers all live on coarse, bulky food, the quantity rather than the quality being the chief item of importance. The class of people in whom the disease is chiefly seen are the colored races, and, therefore, more liable to pigmentation than those races in whom pigment is not usually present in the skin. From the above facts I am of opinion that this pigmentation of the tongue and buccal mucous membranes and mucous membrane of the intestine has some connection with the disease and may be taken as of diagnostic value, as I have never failed to find the ova and the other symptoms of the disease present in any case which showed this pigmentation.

Another view of its causation may be taken in the dermatitis or "chauffie" affecting the laboring class in this island and which without doubt is the true method of infection, pigmentation of the skin affected takes place so that in this island, where the class affected are dirty in their habits and careless as to what they eat or drink, unwashed fruit and vegetables, muddy drinking water is one method of infection, as during the rains the water supply, which usually consists of shallow wells and ponds, is contaminated to a large extent, and as the larvæ do not take very long to penetrate the skin, as seen from Claude Smith's experiments, it may be possible that, when taken into the mouth, they make their way more easily and quickly into the mucous membrane, and that these pigmented areas are the points of their entrance.

Case 1.—A. J., aged 19, unmarried, living with his parents, laborer in cocoa estate. Admitted to Colony Hospital, Feb. 2, 1905.

History.—Patient has been ill for the past year with general weakness as he termed it, unable to do much work owing to breathlessness and palpitation. Three weeks prior to admission he had a severe rigor, followed by fever and slight perspiration; fever comes on every day. Has lost flesh and is emaciated. Complexion muddy, lips and buccal mucous membranes very pale, tongue shows minute pigmented spots on lip and sides. Conjunctivæ very pale and scleræ have an icteric tinge, appetite very poor, can only take fluid nourishment, pain and tenderness in epigastrium, nausea and vomiting after food, bowels constipated and have usually been so for the past year. Skin harsh and dry and does not perspire very much, itching sensation over the whole body. Precordial pain and pain in the chest complained of, palpitation marked, with dyspnea in exertion. Dimness of sight, with severe d continued frontal headache and tinnitus aurium. Vertigo and sleeplessness present. Very weak and has not left his bed for the past three weeks. Pulsation of veins in the neck, apex beat depressed and to the left; marked bruit in third left intercostal space. Pulse soft and compressible.

Examination of Feces.—Ova of uncinaria present in large numbers with those of *Ascaris lumbricoides* and *Tricocephalus dispar.* No blood in the stools.

Examination of Blood.—Malaria Estivo-autumnal parasite present. Eosinophiles, 20; polymorphonuclear, 58; large lymphocytes, 10; small lymphocytes, 12.

Temperature on admission, 102.6, rising on the day after to 104 degrees. No marked rigor or diaphoresis.

Diagnosis.—Ankylostomiasis or uncinariasis. Complication, malignant malarial fever.

Treatment.—Saline aperient every morning. Hypodermic injection of quinin. bihydrochlor. grs. 5 every morning at 10 and in the evening. Diet: Milk, beef tea, arrowroot, etc.

Course.—Temperature still continued. February 17 blood re-examined and found free of malarial parasites. Temperature, 99.8. Feces contained the ova in numbers. February 20, 120 grs. thymol given in cachets of 40 grs., followed by a saline aperient, four hours after the last dose, stools carefully washed and found to contain large numbers of worms. Temperature reduced, but still above normal. Thymol repeated February 23 and stools examined worms still being passed.

Repeated thymol February 26 and 28, and after the last dose only a few worms (6) were found in the last stool.

Feces examined March 2, no ova present, but thymol repeated once more and a week later they were again examined, but no ova present, similarly on the 17th.

The diet was now changed, as appetite had increased, after the second dose of thymol the headache disappeared and the tinnitus was very much decreased, and patient slept well at night. He was now put on the following mixture as well:

℞.	Tinct. ferri perchlor	ʒiiss	10
	Liq. arsenitis hydrochlor	ʒi	4
	Mag. sulph	ʒiv	15
	Syrupi aurantii	ʒiss	6
	Aquæ q. s. ad	℥viii	240

M. Sig.: One tablespoonful three times a day after meals.

Blood examination, March 2: Eosinophiles, 15; polymorphonuclear, 65; large lymphocytes, 10; small lymphocytes, 7. Hemoglobin percentage, 22.

Blood examination, March 31: Eosinophiles, 13; polymorphonuclear, 45.5; large lymphocytes, 14.8; small lymphocytes, 26.2.

Patient is doing well, has gained weight and flesh, all symptoms have disappeared, skin moist. Rapid and uneventful convalescence.

Case 2.—R. G., aged 36, married, children, laborer.

History.—Patient has been ill for past six years, gradually getting worse each year; weakness, fever, breathlessness and palpitation, disinclination or inability to work. Husband and children also affected similarly. Has had "chauffie" very often, particularly after or during the rains. Appearance plump and well nourished. Very anemic; has been very ill for the past month; bedridden; brought to hospital in a chair.

Examination.—General anasarca very marked, ascites developed, face and scalp puffy and edematous. Says she never perspires, appetite lost, pain and tenderness in epigastrium, vomiting after food. Tongue very pale and white, teeth indentatious on tongue, numerous minute pigmented spots on lips and sides, with bluish streaks on side as well.

Superficial veins of abdomen distended, diarrhea, feces yellowish brown, no blood; on examination ova of ankylostoma and ascarides were seen. Liver enlarged, abdomen tender on pressure, ascites present. Precordial pain and pain in the chest very severe, dyspnea extreme, cough troublesome, bases of lungs dull on percussion.

Extreme vertigo, marked tinnitus aurium with severe continued frontal headache, sleeplessness and has had fainting attacks.

Vision dim, great weakness. Heart markedly dilated, with bruits, pulsation of veins in neck; apex beat full and diffused. Pulse 110, weak and dicrotic. Urine normal, patient quite sensible, but prefers being left alone. Temperature on admission 97.8.

Diagnosis.—Ankylostomiasis, chronic.

Treatment.—Milk and beef tea, stimulants.

Patient did not do at all well, and died suddenly on the second day after admission.

Blood Examination.—Eosinophiles, 8; polymorphonuclears, 56; large lymphocytes, 6; small lymphocytes, 30. Hemoglobin, 10 per cent.

Morbid Anatomy.—Lungs: Very pale, but otherwise normal; bases edematous and pleural cavities contained about 2 pints of straw-colored fluid.

Heart: Pericardium contained 4 ounces of serous fluid. Heart very much enlarged and dilated; cavities filled with soft dark clots. Fatty degeneration present in the walls; valves inefficient.

Liver: Enlarged, pale and fatty degeneration present. Abdomen contained large quantity of ascitic fluid.

Spleen: Slightly enlarged, pale but otherwise normal.

Intestines: Jejunum and duodenum both contained large quantities of the worms, most of which had dropped and were lying in the lumen of the bowel. Mucus present in large quantities. Large intestine contained dark yellowish brown fluid feces. Intestinal wall thin and atrophied in parts, presenting large numbers of minute hemorrhagic and pigmented spots.

Stomach: Signs of chronic catarrh present; no worms in the cavity itself.

Kidneys: Pale and otherwise normal.

Brain: Anemic and ventricles filled with fluid. Pia mater stripped easily off the cortex, serous fluid beneath it filling the sulci.

Death in this case was due to mitral inefficiency, resulting from dilatation of the heart caused by chronic uncinariasis or ankylostomiasis.

TREATMENT.

Thymol is the drug employed by me and I have had the very best results with no single ill effect even in children. The dose usually given by me varies with the age of the patient and also his general condition; it ranges from 10 grains to a child to 40 grains for an adult at a single dose.

The following is the procedure adopted by me at the Colony Hospital: The patient is carefully prepared for three or four days after admission, the bowels are kept active by saline aperients administered every morning in sufficient dose to cause one evacuation, the diet is light and easily digested, viz., milk, beef tea, arrowroot, etc., with pepsin if required. In very advanced cases with cardiac troubles, stimulants and cardiac tonics administered. The chief object in the administration of the aperient being to get rid of the mucus with which the intestine is often loaded and in which the parasites lie buried.

At 10 p. m. on the night prior to the administration of the thymol a dose of saline aperient is given and no food except a pint of milk given to the patient next morning and two hours afterwards the first dose of thymol is given. I give it in the form of cachets each containing five grains for a child and 40 grains for an adult and one cachet is taken every hour till 15 grains are given to the child and 120 grains to the adult. In old people and very advanced cases in adults I usually give 30 grains instead of 40 grains. No food is allowed the patient and four hours after the last cachet is given a saline aperient is given and the patient allowed his diet. The stools are collected and carefully washed and invariably show a large quantity of worms, in the case (1) described by me 500 worms were passed after the first administration of thymol. The above treatment is carried out on three alternate days, occasionally an interval of four or five days is allowed in debilitated cases; the feces are carefully examined for ova a week afterwards and usually found free of ova. The feces are again examined two days before the patient is discharged and it is my invariable practice to give another single dose of thymol and to carefully examine the stools again. The after-treatment of the case consists in the administration of tonics, chiefly iron and arsenic, often combined with strychnin; the diet is increased, but is still one which is easily digested and nourishing and usually the patients seek their discharge in from a fortnight to three weeks after the feces are free of ova; and are recommended to continue the tonic at their own homes for a still longer period. I usually administer the iron and arsenic in the form mentioned in the report of Case 1, above, as I find it gives the best results in a shorter period of time.

The saline aperient used by me and which is preferable to any other aperient is the following:

℞. Sodii sulphas.
Mag. sulphas., āā.....................ʒiss | 6
Aqua ad ....℥ii | 60
M. Sig.: Drink.

As I have previously stated, I have had no ill effects from administering thymol, although a few cases have complained of dizziness and a sensation of fainting, but it has gradually passed off; it is, as we know, a very insoluble drug except in spirits and oils and therefore is not absorbed in sufficient quantity to cause toxic effects, besides which the saline purge given shortly after the last dose hurries it out of the system although sufficient time has been given the thymol to act on the parasites, and besides this there is no doubt that sodium or magnesium appears to be an antidote.

A remarkable fact and one which confirms me in the use of thymol is the immediate relief given by the first administration of the drug, from the severe headache and other mental symptoms, the patient next day feeling much brighter and better. Bentley recommends and prefers betanaphthol to thymol. I have not tried this drug as yet, being so far satisfied with my results from thymol, but I intend giving it a trial and comparing the results.

PROPHYLAXIS.

In this island the two chief factors in the causation of this disease are (1) muddy and infected drinking water; (2) soil pollution and infection through the skin. With regard to the first, it has been doubted whether this factor is a true one, yet I have had two cases of this disease in which there was no history of dermatitis, the patients being fairly well to do and not exposed to the second method of infection, but they admitted that the first cause might be the real one, as the water supply was obtained from shallow wells, liable to infection and especially during the rains was often muddy.

However, there are only three methods of prevention, viz.: 1, prevention of water infection; 2, prevention of soil infection; 3, treatment of all cases of the disease.

The two last are the chief ones. In this island the disease is widespread throughout all the districts, especially on the estates and in certain villages, hence the chief essential is the prevention of the fecal contamination of the soil in order to eradicate the disease; the promiscuous depositing of feces near the huts and villages and in the fields should be prevented, but owing to habit and the low intelligence of this class, it seems an impossibility. On all estates where huts are provided for the laborers and other families easily accessible privy accommodation should be provided, pits and trenches would do, which could be filled in from time to time and fresh ones opened. Another point is to try to destroy all ova and larvæ on heavily infected fields by ploughing the earth over and burning bush fires over it and replanting, but as most of the cultivation here is cocoa this is an impossibility; these cocoa groves are the chief infected areas, as here the ova have the ideal humidity, shade and temperature for their growth and development. The people should, therefore, be made acquainted with the danger of depositing feces promiscuously and thus infecting the soil and the liability of their acquiring the disease owing to the nature of their work, barefooted. The next point is the proper examination and treatment of all cases of the disease. On all estates and in villages an examination of all cases of dyspeptic troubles, dermatitis and anemia should be made and the feces examined and if the ova are found, immediate treatment of the case begun so as to prevent their becoming a source of danger to others who are not infected. This can not be done without an outlay on the part of the estate owner or the government itself, but there is no doubt that to thoroughly eradicate this disease such measures must be adopted; otherwise the treatment of cases individually is of little use, for as soon as they are cured and go back to their work, they are reinfected again.

DISCUSSION.

Dr. V. A. Latham, Chicago, said that the southern parts of this country were now confronted with this condition. In patients with ankylostomiasis the whole system stops developing; they are anemic, frail and almost infantile in their actions and characteristics.

Dr. Eugene Talbot, Chicago, said that two or three similar cases have occurred in this country, but not enough to warrant the conclusions brought out by Dr. Leonard. One occurred lately in southern Illinois.

THE PREVENTION OF SUMMER DIARRHEA.*

MAURICE OSTHEIMER, A.B., M.D.,
Instructor in Pediatrics, University of Pennsylvania; Assistant Visiting Pediatrist and Physician in Charge of the Children's Dispensary. University Hospital; Assistant Physician in the Medical Dispensary, Children's Hospital; Assistant Medical Inspector, Bureau of Health.
PHILADELPHIA.

During the hot summer months, the mortality from diarrhea among infants and young children is very great. Attention has frequently been called to this during the last five years, and much has already been accomplished by the health officials of the large cities of the United States in the prophylaxis of summer diarrhea.

Summer diarrheas are due chiefly to two causes, unclean food and hot weather. Bacteria of various sorts, whether introduced from without in the food, or already present in the intestine, are undoubtedly the exciting causes; but they seem unable to act deleteriously until the vital resistance of the child has first been decidedly weakened by protracted heat or humidity. Hot weather may also bring about deterioration of the milk, which forms the baby's usual food, by favoring the increased production of bacteria in the milk.

As the chief cause of what Dunn[1] so aptly calls "thermic diarrhea" is the heat, our efforts in the prevention of summer diarrhea must be directed toward overcoming the heat, so far as is possible. On the appearance of the first sign of any gastrointestinal derangement, all milk must at once be stopped and barley water or whey given.

Parents, educated or ignorant, poor or rich, must all be taught many things, among others, to bathe infants regularly and often; to keep excessive clothing off; to keep them cool and in the open air; not to disturb them unnecessarily, for playing or petting, so that they secure sufficient sleep; to attend to soiled napkins early; and to realize the importance of keeping off flies. Correct breast and bottle feeding, the correct frequency of feeding, the correct quantity to be given at correct intervals, the correct cleansing of nipples and bottles, the furnishing of a "clean" milk, the precautions necessary to keep it clean, etc., must be taught and must be so clearly expressed that they are plainly understood by all.

This is perhaps best accomplished by the judicious distribution of printed pamphlets containing instructions to mothers for the care and feeding of infants during the heated term. Of the fifteen largest cities of the United States, all containing over 250,000 inhabitants, such booklets are now distributed only by nine: St. Louis, Baltimore, Cleveland, San Francisco, Cincinnati and Pittsburg not as yet issuing any. Four cities have them printed in several languages: Chicago, in English, German, Bohemian, Polish, Swedish, Norwegian, Italian and Yiddish; Buffalo, in English, German, Polish and Italian; New York, in English, Italian, and Yiddish; and Milwaukee in German and English. Philadelphia, Boston, New Orleans, Detroit and Washington have the pamphlets printed in English only. Those distributed in Boston are dated 1879: those in Chicago, 1895, and those in New Orleans, 1899. Those now issued in New York and Washington were printed in 1904; those in Philadelphia, in 1905.

I wrote to the health officials of the nine cities containing from 150,000 to 250,000 inhabitants, but received no answer from Newark, Louisville, Indianapolis or Kansas City, which cities, I presume, do not issue any such pamphlet. St. Paul does not, either. In Minneapolis and Jersey City the pamphlets are printed in English only; in Providence, in English, French and Italian; and in Rochester, in English, German, Italian and Yiddish.

It would seem advisable to have special "milk" courses given in the public schools, the high schools especially, and in the medical schools and hospitals, for the instruction of growing children, physicians and nurses. The fact that clean milk can be procured will then be recognized. In cities in which such milk is obtainable, as the result either of municipal or private enterprise, the public will notice the difference between ordinary dirty milk and that receiving certificates from a milk commission such as is already in existence in many cities. This milk is kept up to standards which are vouched for by an expert bacteriologist, an expert chemist and an expert veterinarian. Such certified milk must be free from pathogenic micro-organisms and contain not more than from 10,000 to 30,000 to the c.cm., varying in several cities; its specific gravity must be between 1,029 and 1,033; its reaction must be neutral or faintly acid; its proteid should vary between 3.5 and 4 per cent.; its sugar between 4.2 and 4.8 per cent.; its fat between 3.5 and 4.5 per cent.; and it must be free from impurities, coloring matters and chemical preservatives. Besides, the condition of the dairy and the cows must be kept excellent.

In order to supply such clean milk to rich and poor alike, it would be well for every large city to acquire a dairy in the outskirts of the city, to be run on modern methods, under the guidance of a milk commission. Such a dairy might come under the jurisdiction of the municipal health department, and the city bacteriologist could easily watch that the milk and cream there prepared be kept up to the standard required. Each city could then supply clean milk to its citizens, and a municipal laboratory might be established for the preparation of mixtures which could be ordered by any physician on prescription blanks, free, or at a nominal price to the poor, at ordinary prices to those able to pay.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Charles H. Dunn: "Etiology and Classification of the Summer Diarrheas of Infancy." Archiv. of Ped., June, 1905.

Should the powers that be object to the expense of such an undertaking, such a dairy, and possibly laboratory also, could be established by private subscription for the use of the poor only. Something like this was attempted in St. Louis last summer. As, at that time, there were no stringent regulations to standardize the cream and milk used, the purity of the mixtures prepared may be questioned. Rules have since been adopted, however, by the St. Louis Milk Commission, which will bring the milk and cream up to the standards maintained by the milk commissions of Eastern cities. While these modified mixtures have been distributed in St. Louis to anyone bringing a physician's prescription, milk funds, limited in distribution to the patients of certain hospitals or dispensaries, have for some years been in operation in Boston, Baltimore and Newark, with success.

In New York and Philadelphia, Mr. Nathan Straus gave the plants in which are prepared the modified mixtures distributed in both cities. Unfortunately, he has insisted on the pasteurization of all mixtures. Recent researches by Pennington[2] prove that commercially pasteurized mixtures, though prepared from clean milk and cream, contain after pasteurization more bacteria than before. Bergey,[3] Evans and Cope[4] have also shown the practical uselessness of pasteurization and sterilization, when performed more than from four to eight hours before the mixture is to be used. These researches do not, however, reflect on home pasteurization, correctly performed, in closed, filled bottles, when for any reason it is feared that the milk is not clean. How much better off would the community be, were we able to furnish a clean milk to all, so that neither pasteurization nor sterilization need even be thought of! Sterilization causes decided changes, those which occur whenever milk is boiled, and should never be employed; while pasteurization, always an iniquity, though occasionally a necessary iniquity, can also be dispensed with when clean milk and cream are used.

The simplest method for distributing milk and feeding infants in hot weather is that established in Rochester, in 1900, by Dr. George W. Goler. His efforts led to the furnishing of a clean milk and from that time pasteurization has been omitted. Several months ago, an association for the improvement of the milk supply of New York City was formed by 40 of the largest milk dealers, to assist the health department to secure clean milk. This society intends to educate the farmers and then to inspect the dairies regularly.

After studying the municipal pamphlets already in existence, I have prepared the following sample pamphlet for distribution by municipal health departments. In this I must acknowledge my indebtedness to the departments of health of Rochester and of New York City.

On the outer cover should be the name of the city, with the words "Health Department," "Department of Health," or "Bureau of Health," followed by the title of the pamphlet "Instructions to Mothers for the Care and Feeding of Young Children During the Hot Weather."

Inside the cover should be the following:

Clothing.—During the very hot weather infants should wear only a napkin and a thin gauze shirt. An abdominal binder, of thin flannel, may be worn until the child is six months old.

No infant should ever wear starched, stiff, uncomfortable clothes; everything should be loose.

Clothes worn during the day should be washed and hung out to air at night, while those worn at night should be washed or aired during the day.

Bathing.—Every young child needs at least one tub bath every day. On very warm days babies should be sponged two or three times a day with luke warm or cool water, containing a teaspoonful of salt to a pint of water, or a little alcohol or vinegar.

Poorly nourished infants should also receive a mild general rub with sweet oil once daily, after the morning bath.

The baby should be bathed before feeding; never bathe a child soon after feeding.

Talcum powder may be used freely after the bath. If slight chafing occur, stop using the powder and smear the parts well with boric ointment; if the chafing persists, consult your physician.

Fresh Air.—Fresh air is of vital importance. Keep the windows open. Never keep a child in a close or crowded room.

Have the child in the open air all day during the hot weather, out of the sun, protected from strong winds, bright sunlight and flies.

Whenever possible, if advised by your physician, take a trip on the water, to the country or seashore. Trolley rides are of value, provided you protect the infant from strong winds.

Instead of sweeping the baby's room, mop furniture, walls and floor with a moist cloth. This does not raise dust, which might contain germs.

Sleep.—Every young child should have twelve hours sleep at night. Naps of about two hours, morning and afternoon, should be insisted on until the child is 3 years old.

Each child should sleep by itself, in a crib or coach; this is most important in warm weather, when the heat of the mother's body, lying near, keeps the baby too hot.

Soiled Napkins.—Napkins should be changed frequently, just as soon as soiled. They should be placed in some covered receptacle, in water, and should be washed and boiled as soon as possible.

Never use oilcloth or waterproof materials for napkins; they keep the child's body hot and moist.

Do not wash or dry napkins in the room occupied by the baby.

Flies.—It is important to keep flies away from children and their food. For flies come from dustbins, manure and refuse heaps, readily carrying germs to children and into their food, when it is left uncovered. Windows and doors should always be screened and the baby's crib should be covered with mosquito netting. Whenever the child is taken out, the coach should be covered with netting to protect the baby from mosquitoes and flies.

Breast Feeding.—Always nurse your baby unless your physician advises you not to.

Keep your nipples scrupulously clean, washing them with cool boiled water before and after each nursing.

Each breast should be nursed at alternate feedings; both breasts should not be given the infant at one feeding unless specially ordered by your physician.

The mother's bowels should be moved once daily; she should take three plain, well-cooked meals a day, of milk, cereals, meat and vegetables. She needs plenty of milk and water; but she should not take tea, strong coffee, or liquor.

In very hot weather, or when overheated, she should "milk" her breasts, throwing away several teaspoonfuls of her milk before allowing the child to nurse.

Bottle-Feeding.—Procure the cleanest, freshest milk possible. Where possible, use certified milk. Do not skim the milk. Clean milk and cream are delivered in covered bottles. These should never be allowed to stand uncovered; nor should milk ever be carried in an uncovered receptacle. For dust or flies, both bearing germs, may enter it. Milk and cream should always be kept cold; in a refrigerator when possible; if you have no ice, wrap a cloth wrung out of cold water around the bottle.

Have the baby weighed every week up to six weeks of age; then every two weeks, regularly; and feed it according to the following table:

2 Tablespoonfuls, 1 ounce; 4 teaspoonfuls, 1 tablespoonful.

Weight.	Milk.	Barley Water.	Granulated Sugar.	Intervals between feeding	From 6 a. m. to 6 p. m.	From 6 p. m. to 6 a. m.
From 6 to 8 lbs Under 3600 g.	1 oz....	2 oz....	½ teaspoonful	2 hours	6 bottles.	2 bottles.
9 and 10 lbs. 3700-4500 g...	1½ oz..	2½ oz..	½ teaspoonful	2 hours	6 bottles.	2 bottles.
11 to 14 lbs. 4600-6400 g...	2½ oz..	2½ oz..	¾ teaspoonful	2½ hrs.	5 bottles	2 bottles.
15 and 16 lbs. 6500-7300 g...	3½ oz..	2½ oz..	1 teaspoonful..	2½ hrs.	5 bottles.	2 bottles.
17 and 18 lbs. 7400-8200 g...	5 oz....	2 oz....	1 teaspoonful..	3 hours	5 bottles.	1 bottle..
19 and 20 lbs. 8300-9000 g...	8 oz....	0 oz....	1 teaspoonful..	3 hours	5 bottles.	1 bottle.
21 and 22 lbs. 9100-10000 g..	10 oz...	0 oz....	½ teaspoonful	2 hours	5 bottles.	0 bottle.

In every case make one-tenth of the mixture lime water; this may be procured at any drug stone. It is added to prevent vomiting.

Barley water is made by boiling whole barley, two tablespoonfuls, or barley flour, one tablespoonful, for 15 or 20 minutes, in one pint of water; strain and add boiled water to make one pint again. This is used both to dilute the milk and to help the baby digest the cow's milk.

Should the baby fail to gain in weight at the end of two weeks, clean cream may be added cautiously, beginning with one teaspoonful to each bottle, and gradually increasing. Your physician will tell you how much cream you may add; as a rule, more than one-tenth of the mixture should never be added. (For example, a baby weighing 8 pounds gets 3 ounces, 6 tablespoonfuls, or 24 teaspoonfuls, at each feeding. More than one-tenth of this quantity, i. e., 2½ teaspoonfuls, of cream should never be added.) If you are not sure that the cream is clean, boil it; and boil the sugar and water, too; then add them to the clean milk when cold.

Should the baby develop vomiting or diarrhea, stop all milk at once and give barley water only until whey can be made. If your physician advises it, prepare the whey by adding one teaspoonful of liquid rennet or essence of pepsin to one pint of milk which has first been heated. Or dissolve one rennet tablet in one ounce of cold water and add this to one quart of milk; then heat it to about 100 F., and allow it to stand. When the curd has become solid, beat it up well with a fork, and keep it warm for 10 or 15 minutes longer. Then strain and put the whey on ice.

Some days later, if your physician advises it, add one teaspoonful of milk cautiously, to each bottle, after having heated the whey up to 155 F., to stop the further action of the rennet. The quantity of milk or cream to be added, later, is to be regulated by your physician.

Whoever prepares the food should wash her hands regularly before beginning to make the mixture.

Before each feeding the bottle is heated in water, resting on a saucer, until the water under and about the bottle begins to boil; it should not be allowed to boil. The bottle is then removed and allowed to stand, to cool off somewhat before the baby gets it.

Before taking the breast or bottle, the baby's mouth should be cleansed with cool boiled water. Between feedings every child, whether breast or bottle fed, should be given cool boiled water to drink, frequently, from several teaspoonfuls to a tablespoonful at a time.

No child should be fed more frequently than here given, nor should a larger quantity be given at any feeding without the special advice of your physician. When any milk remains in the bottle, always throw it away; do not heat it over again.

When the warm weather begins, it is a wise precaution to reduce the strength of mixtures given bottle-fed babies, in fat especially, as a child is often unable to digest its regular food during hot weather. *This alone may prevent illness.*

All nursing bottles should be cleansed thoroughly, first with cold water, then with washing soda and hot water; and then rinsed well and boiled before using. Nipples should be turned inside out and scrubbed in cool boiled water and borax, 10 grains to the ounce, with a brush used for this only. All nipples should be boiled once daily. At least six bottles are needed. After cleansing them, stand them upside down on a shelf. The nipples should be kept in cool boiled water, in a covered receptacle. Bottles with twisted necks and nipples with tubes should never be used.

Weaning.—When the child is 10 or 12 months old, it should be weaned, except in hot weather, when the breast or bottle may be continued until the autumn. Weaning is accomplished by substituting pure milk, or a modified milk mixture when ordered by your physician, in a cup or glass, for the breast or bottle, once daily at first; then twice, increasing gradually until the child only takes milk by the glass.

Feeding After First Year.—At 1 year of age, two, and later four or five meals a day may be given, gradually increasing the amount at each feeding. The meals should be composed of some of the following: Milk, stale bread or toast with butter, soft boiled eggs, strained beef, mutton or chicken broth, and cereals (oatmeal or hominy cooked three hours; cornmeal cooked two hours; or farina cooked one hour).

At 2 years of age meat may be added cautiously. The child should then take only three meals a day, with water or milk regularly between meals. Supper should consist of milk, bread and butter, and a cereal.

No child should ever be given tea, coffee, or liquor; fried food of any kind; griddle cakes, sausage or pork; heavy, doughy puddings, fresh bread, cake or pastry; unripe, sour or over-ripe fruit; bananas; very sweet preserves, popcorn, candies, etc.

Too much food is always worse than too little, especially *in hot weather.*

Never give a baby sleeping drops, anodynes or soothing syrups.

Never allow children to creep about on the floor; for there is danger of cold draughts of air, and of dust containing germs.

Let the baby alone; don't disturb it unnecessarily, to play with it, pet it, or handle it.

Have the baby vaccinated before it is 1 year old.

Summer Diarrhea.—If the baby passes several loose stools, with or without vomiting, the child needs medical attention.

Stop all milk food at once, and give the baby boiled water or barley water, if less than 1 year of age; or whey if over 12 months, until it can be taken to a physician.

Even simple cases of vomiting and diarrhea should never be neglected, for the disease is often mild at first, without any sign of illness other than diarrhea; yet, in a few hours, the baby may be dangerously ill.

If you have no physician and there is no hospital near, telephone to the Board of Health and a district physician will be notified.

The objection which can be raised to this method of simply diluting milk is, of course, the very low fat percentage in the mixtures; but this, as a rule, is just what is needed during hot weather.

When the baby fails to gain, small amounts of cream can easily be added. The objection to this, however, is the fact that the cream, in hot weather especially, will contain far more bacteria than the milk. This objection may be overcome by boiling the small quantity of cream separately, by boiling sugar and water, and by adding them, cold, to the clean milk. If the baby then has indigestion it may be due to too much fat, but it is more probably due to the infant's inability to digest the caseinogen of cow's milk. This, however, is much decreased by the use of whey, which can be easily prepared. The proteids can then be raised easily, with a very gradual increase in the fats, by adding milk; or the fats may be raised rapidly by adding cream.

The manner of distributing these pamphlets also needs consideration. They should be given away by both district physicians and medical inspectors. Whenever, in hot weather, either has occasion to visit a home in which there are children under 3 years he should not forget to leave a pamphlet. The pamphlets should also be sent to dispensaries, and milk and ice stations for free distribution. Some should also be sent to every physician in the city, for the benefit of his patients, and he should be informed where more can be procured. In cities with a large foreign population much can be done by having the pamphlets printed in several languages. It seems important also to have these instructions reach the well-to-do as well as the poor, for it is only by furnishing clean food and educating mothers and nurses that summer diarrhea can eventually be overcome.

225 South Twentieth Street.

DISCUSSION.

DR. C. F. WAHRER, Fort Madison, Iowa, declared that every case of summer diarrhea is a case of itself; there are so many known and unknown factors such as surroundings, predisposition and food. Two of the principal reasons of an increased number of cases in the summer are increased putrefactive changes in foods of bacterial origin, and the worry and disturbance to the nervous system. He said that he went out to see milking done at one of the finest hotels in Yellowstone Park. The cows were deep in the mire that they made themselves. He saw the milkman come out, unkempt, unwashed, pick up a milk stool, give a cow a kick, stroke the udder and begin to milk. The whole place was literally covered with what in the Anglo-Saxon would be called "cow dung." Much of the milking on farms, Dr. Wahrer believes, is done in the same manner so that the milk is mixed with the filth, hence it is very difficult to control the supply of milk to bottle-fed children. In the larger cities mothers who are subjected to work akin to that of the beast of the field are nursing their children. Such a mother can scarcely give healthy milk, and the unsanitary mode of life of the mothers should be changed. Dr. Wahrer agreed with Dr. Ostheimer that education is necessary. He does not think any mother would transgress the rules of cleanliness, etc., if she were taught the importance of the care of the milk supply.

DR. L. M. SILVER, New York, said that in New York City there is a list of charitable summer work for children. Mothers interested are given cards of admission. Each mother is given a printed slip with instructions for the care of milk and for the preparation of barley water.

DR. KATE LINDSAY, Boulder, Colo., stated that her practice has been mostly in the farming districts, and that there the ignorance with reference to infant feeding is quite as lamentable as in the cities. As an illustration she related one of her cases. She was called to see a child with summer diarrhea. At the same time a veterinarian was called to see a colt. The farmer was in a great rage because his best mare had been driven and overheated. At the same time he required his wife to cook for sixteen men and to sweat over the fire. Dr. Lindsay examined the milk and found it deficient in every way. Education along this line is needed among the farmers of the country. Dr. Lindsay would not discourage efforts to educate the people of the slums, but asked why we should not take care of the best as well as the worst in the land.

DR. G. BLUMER, San Francisco, said that there are a few cases of summer diarrhea in San Francisco, occurring usually after the occasional hot spells in that city.

DR. ARTHUR W. FAIRBANKS, Boston, asked Dr. Ostheimer how long he keeps the children on a cereal mixture. There is always some uncertainty in Dr. Fairbanks' mind on this point. He also asked what the indications are for taking the child off the milk, whether it is fever, temperature or general septic signs.

DR. A. C. COTTON, Chicago, said that all physicians appreciate the idea of the education of the laity by means of pamphlets. He believes that health department work has obtained some of its best results through the circulars issued to mothers. Dr. Cotton would put such instructions in a place of honor and have the mother taught to look at them as her lode star. The mothers should be taught particularly that there is a beginning to this trouble, and that often this is in the method of nursing or feeding. The little regurgitation which comes with too rapid feeding will cause indigestion and summer diarrhea follows. For summer feeding the food should be diluted. A lower caloric value of the food is needed. In artificial feeding we are not feeding according to nature, but according to experience, and attenuated food is more easily digested.

DR. JOHN LOVETT MORSE, Boston, declared that he objected to the title, "Prevention of Summer Diarrhea." He thinks it ought to be "Prevention of Diarrhea in Summer." He stated that it should not be forgotten that whey is milk and that bacteria will grow in one as well as in the other.

DR. MAURICE OSTHEIMER, in reply to a question, stated that the length of time the child is kept on barley water depends on the symptoms. It may be from twenty-four to forty-eight hours; in extreme cases perhaps seven or eight days, but in these cases he should add brandy or whisky, so that the baby gets some nourishment. In most cases, however, he gives no alcohol while on barley water. On the first sign of gastrointestinal derangement he would stop the milk, even if for only twenty-four hours. As Dr. Cotton has said, the regurgitation of food is one of the first signs of trouble and ought to attract the mother's attention. In reply to a question Dr. Ostheimer stated that when pasteurization is done in bulk the bacteria are increased tremendously. Whether they are the same bacteria which are found in the beginning he does not know; whether they are pathogenic is another question; he does not believe that they are. In Philadelphia a great deal of work has been done in this connection, and the importance of keeping milk clean has been proved.

FIFTEEN CASES OF SUMMER DIARRHEA.*

JOHN C. COOK, M.D.

CHICAGO.

The fifteen cases of summer diarrhea which I wish to present, have been selected from the two hundred and fifty cases of children's diseases that came under my observation at the Jackson Park Sanitarium, Chicago, during the months of July and August, 1904. For the sake of brevity I will divide these cases into two classes. The first class comprised eleven cases of a mild type, the records of which have been combined in such a way that they will serve as a standard of comparison by which to estimate the value of the findings in the remaining cases. The second class comprises four fatal cases which are of special interest because of the bacteriologic and microscopic findings both during the clinical course and at postmortem.

As briefly as possible, I will relate the findings to which I wish to call attention. The average age of these infants was nine and one-third months. Personal and family history is what would be expected in a class of charity patients, breast fed by poorly nourished mothers, and artificially fed on every sort of milk and infant food. The average course of temperature is shown in Chart 1; it varied from 97 to 102.5 F., with a total average of 99.4. Vomiting was present, but was not by any means a constant symptom. The frequency of

In the stools of this case a Red Pigmenting Bacillus of the Colon Group was isolated. This pigment stained the stools blood-red but no blood was found upon microscopical examination.

bowel movements also I have placed on Chart 1. They varied from two to seven a day, with a total average of four. Lesions were present in the mouth in three of the eleven cases, but were mild and readily yielded to treatment. The differential blood findings were as follows: Small lymphocytes 27 per cent., large lymphocytes 16 per cent., neutrophiles 53 per cent., eosinophiles 2 per cent., myelocytes 2 per cent. The parasitic and bacteriologic findings of the stools were as follows: The pneumococcus was present in seven cases, sarcina in four, colon bacillus in seven and unidentified bacilli in ten, yeast in three and mycoides in one, with a total of three varieties in each case. Of the bacteriologic findings of the throat, the pneumococcus was present in seven cases, sarcina in four, colon bacillus in six, yeast in nine, unidentified bacilli in two and thrush fungus in one. There was a total average of three varieties in each case.

I will now take up the findings of the second class of cases. The first of these was a male, aged 6 months. No history was obtained; the child was under observation from July 16 until his death, August 7. The temperature range, which is shown on Chart 2, was moderate, from 97.8 to 103.5 F., averaging throughout the course of the disease 99.6. As is also seen on Chart 2, there was a range of from two to seven bowel movements daily, with an average of four. Lesions in the mouth were constantly present. Vomiting occurred in the last five days only. Neither blood nor bacteriologic examinations of the stools and throat were made during life, but the microscopic and bacteriologic examinations postmortem are important. The microscopic examination of the lungs showed well marked bronchopneumonia. In the kidneys a diffuse parenchymatous nephritis had developed. The small intestines showed an exfoliation of the epithelial and mucous coats with a round cell infiltration of the muscular layer. Bacteriologic examination showed the presence of the pneumococcus in every organ, as well as in the blood and peritoneal fluid.

The second of the severe cases was a female aged three months. This case was under observation from July 29 and came to autopsy August 10. The child had been fed on a proprietary food, otherwise the history was negative. As can be seen by Chart 3, the temperature course was very mild, between 98 and 101.5 F., averaging about 99 degrees. The bowel movements averaged six a day, reaching the highest number, nine, six days before the child died. Vomiting occurred three times. Lesions of the mouth were present during the last days of the disease. The differential blood findings were as follows: Small lymphocytes 38 per cent., large lymphocytes 20 per cent., and neutrophiles 42 per cent. There was in all, four varieties of micro-organisms in the stools, the colon bacillus, an unidentified bacillus, the pneumococcus, and the thrush fungus, which was very abundant. In the throat also four varieties were demonstrated—the colon bacillus, pneumococcus, sarcina, and thrush fungus. An autopsy was held, which resulted in the disclosure of a bronchopneumonia and a parenchymatous diffuse nephritis. The bacteriologic examination of the organs showed the presence of the pneumococcus in the lungs. The other organs were sterile.

The third of the three cases was a female aged 2½ months. This child entered the sanitarium August 5 and died August 29. The mother of the child had been in an insane asylum with puerperal insanity since the birth of the infant, and the child had been fed on Mellin's food up to the time she came under observation. The temperature course was of a septic character, ranging from 98 to 106 F. (Chart 4), averaging about 101 degrees. The bowel movement ran up as high as ten, with an average of six. Vomiting was present, but was not of frequent occurrence. Mouth lesions were constantly present. The differential blood count was as follows: Small lymphocytes 35 per cent., large lymphocytes 15 per cent., neutrophiles 47 per cent., eosinophiles 1 per cent., and myelocytes 2 per cent. Repeated Widal tests were positive. The bacteriologic examination disclosed the specific trouble to be typhoid. The bacteria of the throat were colon bacilli, sarcinæ, and pneumococci three varieties. The bacteria of the stools were colon bacilli, a red pigmenting bacillus of the colon group, typhoid bacilli, sarcinæ, pneumococci and streptococci, six varieties altogether. A postmortem was not obtainable.

The last of the severe cases was a female aged 7½ months. This child came under observation July 22, and died August 5, fifteen days after entering. In this case there also ran a septic temperature which varied from 98 to 104 degrees. Bowel movements were frequent, once reaching fifteen during twenty-four hours. Vomiting occurred only twice and was not severe. No mouth lesions were present. The blood examinations were not made. The bacteriologic examination of the throat was also omitted. One bacteriologic finding in the stools makes this case worthy of notice. There was found a red pigmenting bacillus of the colon group that developed a red pigment so rapidly in the intestines that the feces and mucous secretions were stained blood red. Several bloody stools were recorded and twice the nurse in charge reported a hemorrhage from the bowels, but no blood was found on microscopic examination. A full description of the pathogenesis of this bacillus has not been furnished me, but the clinical significance of such a finding is worthy of some comment. An autopsy was not allowed in this case.

As a result of the examination of the above cases, the histories of which have been briefly reviewed, some general deductions may be made regarding the etiology, symptomatology and treatment of summer diarrheas of children. It will be remembered that Booker, in 1897, made the statement that no single micro-organism is found to be the specific exciter of summer diarrhea of infancy, but the affection is generally to be attributed to the results of the activity of a number of varieties of bacteria. While generally speaking, the statement is undoubtedly true, however, it does seem possibly and probably true that some of the well-known pathogenic organisms, such as the typhoid bacillus, pneumococcus and streptococcus, gain entrance to the general circulation through lesions in the gastro-intestinal tract, and give rise to septicemia, and are the immediate cause of death; that these atria of infection are produced by the local action of less toxic micro-organisms, such as staphylococcus, colon bacillus, yeasts, and thrush fungus; and that the toxins which are generated by the saprophytic action of all of the micro-organisms in the intestines, tend both to lower the resistance of the child and to mask the symptoms of the specific intoxication. It is further apparent that the increased frequency of vomiting and bowel movement is more often due to the reflex action of septicemia and sapremia than to direct intestinal irritation; and that the gross appearance of blood in the stools should always be corroborated by a microscopic and bacteriologic examination.

Finally, if the above conditions of sepsis and sapremia be true in these cases, then the problem of treatment resolves itself into a question of maintaining the general resistance of the child and of neutralizing the specific intoxication by such means as prophylactic cleanliness, nutritious diet, frequent enemas to keep up the balance of body fluid, quinin inunctions as a general tonic, and keeping the child out of doors on a firm bed, instead of on a luxurious crib or cab in a stuffy, hot room.

I wish to acknowledge valuable assistance rendered me in this work to Drs. J. J. Gill and W. G. Baine.

DISCUSSION.

Dr. M. Michael, Chicago, said that with Dr. Coone and Dr. Weaver he undertook the study of 97 cases of summer diarrhea in children. Dr. Weaver took up the bacteriologic side of the question, and Dr. Coone and Dr. Michael the clinical. For collecting the stools a sterile wide-mouthed bottle partly filled with salt solution was used; this was tightly corked and two glass tubes were passed through the cork. One was stuffed with cotton and to the other was attached a rubber tube and to the end of this a catheter. The catheter was protected by a second tube in order to keep it sterile until inserted into the bowel. The apparatus was turned upside down and the second tube was gradually drawn back as the catheter was inserted. When the salt solution had run into the bowel the apparatus was turned down again and the stool passed through the catheter into the bottle. This was carried to the laboratory, and the Memorial Institute for Infectious Diseases of Chicago furnished the material for bacteriologic study. The dysentery bacillus was found in about 24 cases. Clinically the 97 cases could fairly well be divided into two groups. In the first group the toxemic symptoms predominated. There was high temperature, nausea, vomiting, restlessness, great nervousness and the children were very ill. In the second group the local symptoms predominated, the picture being one of ileocolitis. In these cases the stools contained much mucus and blood. The dysentery bacillus was found in the cases in which the stools did not show blood and in those in which the blood and mucus were found, but it did not occur in all the latter cases. They found also that cases of ileocolitis in which the dysentery bacillus was found did not differ in any way from those in which the bacillus was not found.

Dr. Arthur W. Fairbanks, Boston, stated that Dr. Cook's remarks may explain an experience a few years ago in a small hospital in Boston where they have a great many cases of very severe ileocolitis. The nurse reported that blood appeared in the stools of a patient, and Dr. Fairbanks directed the house officer to hunt with the microscope for blood, but it was not found. Later he saw one of the stools and it had the appearance of streaks of blood through it. He then requested the house officer to make the hematin test. The house officer reported that there was no positive reaction, and Dr. Fairbanks inclined to question the accuracy with which the test was made, but this bacillus mentioned by Dr. Cook, he thinks, may explain the occurrence.

Dr. J. C. Cook said that he was glad to have Dr. Michael give the method of collection. Good work was done by her and her colleagues and a valuable report made of it. The bacillus has been examined in a number of laboratories and has shown some peculiarities of growth and development; whether or not it is pathogenic is not yet known. It is believed to belong to the colon group. There is no literature on the subject so far as Dr. Cook has been able to find. It appeared twice in his experience and the quantity of blood or stain was so great that it might easily be mistaken for a hemorrhage of the bowels when there was no blood or ulceration present. In reply to a question Dr. Cook stated that it was a fatal case, and that he, perhaps, did not make very apparent the relation of the vomiting to the rise of temperature. The vomiting and bowel movements were very likely to occur together or within a few hours of one another, showing the condition of sepsis that might induce them rather than any bowel irritation. These children were for the most part fed after the most approved method.

Variable Liver.—Professor Mongour of Bordeaux has noticed that in malaria the liver is liable to vary in size from day to day. These variations seem to be proportional to the resisting powers of the organ. The prognosis of any acute or chronic hepatitis is better the greater the range and frequency of these changes in the size of the liver. In some cases the organ will seem to be atrophied one day and hypertrophied the next. He has recently called the attention of the Paris Academy of Medicine to the matter.

THE ANTI-MICROBIC ACTION OF IODIN.*

GUY C. KINNAMAN, M.D.
Assistant Instructor in Skin and Venereal Diseases,
Chicago Policlinic.
CHICAGO.

PREFACE.

The uniform satisfaction given by the iodin catgut prepared after the method of Claudius,[1] which has been used by Dr. Nicholas Senn in his clinical work, led him to employ a solution of iodin for irrigation in infected wounds and also for hand sterilization. The results obtained demonstrated, clinically, the marked potency of iodin in solution as an antiseptic. Its continued use for several years has shown it to be far superior to any antiseptic previously employed.

In order to determine the absolute value of this solution, a series of experiments have been carried out on a number of different micro-organisms *in vitro.* A sufficient number of different organisms and a great number of tubes have been used. Therefore one is justified in assuming that the conclusions arrived at from a careful study of the series of experiments represent as nearly as possible the position of iodin in the family of antiseptics. When we try to make an accurate comparison between the members of this numerous family, however, we find we can not do so because of the widely different methods of procedure employed by the different investigators. In addition, the majority of the methods show one or more points of possible error. Not for the purpose of comparison, but with the idea in view of presenting the experimental findings of various men on the more important antiseptic substances, there has been incorporated in this research a short bibliography of antiseptics in general.

Bichlorid of Mercury.—Kyle[2] found that it took 1/1000 solution bichlorid ten hours to insure no growth of tetanus bacillus. Koch[3] determined that a 1/20000 solution killed anthrax spores in ten minutes. Klein,[4] however, found that anthrax spores were not influenced by a 1/10000 solution acting for one hour. Evans,[5] from experiments on *Bacillus anthracis* in liquid media, reported that a 1/15000 for one minute and a 1/20000 for thirty minutes were effective. In regard to the spores he found that a 1/1000 for fifteen minutes and a 1/1500 for one hour were effective. Likewise, a 1/1000 for five minutes gave growth. On *Staphylococcus pyogenes aureus,* the same author states that a 1/200 solution for fifteen minutes killed, while a 1/250 solution for one hour impaired vitality. Tarnier and Vignal,[6] using thread method of Koch, found that a 1/1000 solution for two minutes killed both *Streptococcus* and *Staphylococcus pyogenes aureus.* Harrington,[7] employing the same method, states that where the threads are moist an exposure of over fifteen minutes to a 1/1000 solution is necessary to kill the *Bacillus pyocyaneus,* while if threads are dry five seconds are sufficient. On *Staphylococcus aureus,* either on moist or dry threads, from five to ten minutes kills. On *Bacillus anthracis,* either dry or moist threads, an exposure to a 1/1000 solution for thirty minutes has no bactericidal effect. Hence, he states that bichlorid of mercury is a greatly overrated disinfectant. Burgess,[8] who also used the thread method in his experiments on *Bacillus coli communis,* found that a 1/750 solution for one minute was effective, as were a 1/2000 solution for five minutes and a 1/7500 for ten minutes. Sternberg,[9] from experiments on gonococcus, states that 0.005 per cent. bichlorid solution for two hours kills. He concludes that in bichlorid we have a germicidal agent of the highest value.

Carbolic Acid.—Kyle[2] found that the tetanus bacillus had to be exposed to a 5 per cent. carbolic acid solution for six hours in order to assure no growth. Cabbot,[10] on adding 5 per cent.

---

carbolic acid to a putrefactive solution and then transferring several drops of mixture to an aseptic medium, discovered that after five seconds' exposure no putrefaction occurred in fresh tubes. Evans[5] found that on anthrax bacillus a 1/100 solution for five minutes, a 1/150 solution for fifteen minutes, and a 1/175 solution for thirty minutes, were effective. On the spores, he got a growth after four hours' exposure to a 5 per cent. solution. A twenty-four hours' exposure, however, was sufficient to insure no growth. A 1/40 solution on *Staphylococcus aureus* for fifteen minutes gave no growth. Burgess,[5] in his work on *Bacillus coli communis,* states that a 10 per cent. solution kills in one minute, a 2.5 per cent. in five minutes, a 1 per cent. in thirty minutes, and a 0.75 per cent. in one hour. Blyth[11] found that a 10 per cent. solution for four hours had no effect on anthrax spores. A twenty-four-hour exposure, however, prove deficient. He used the glass-rod method. On the gonococcus and micrococcus of abscess pus, Sternberg[9] found that the action of an 0.8 per cent. solution for two hours killed the organisms.

Alcohol.—From experiments on the germicidal effect of alcohol, Harrington[12] concludes: "Alcohol of any strength has absolutely no effect on anthrax bacillus; 60 to 70 per cent. alcohol is the most efficient strength against non-spore forming bacteria, i. e., *Staphylococcus pyogenes aureus* and *albus,* typhoid bacillus, bacillus of diphtheria, being usually effective in five minutes."

Salzwedel and Elsner,[13] using thread method, state that 55 per cent. (by weight alcohol) was most destructive to staphylococcus pus, requiring in fresh pus from five to six minutes to be effective. They state that this solution is not quite equal to a 1/1000 solution of bichlorid, but is as efficient as a 3 per cent. carbolic solution. Sternberg[9] found that with a two-hour exposure, a 95 per cent. alcohol was fatal to gonococci, while a 40 per cent. solution did the work on the micrococcus of abscess pus.

Hydrogen Peroxid.—In his work on the tetanus bacillus, Kyle[2] states that after a forty-eight-hour exposure to hydrogen peroxid the bacillus still grew. On the other hand, Gibler[14] finds, from experiments he has made with a 3.2 per cent. hydrogen peroxid solution in water on *Bacillus anthracis, Bacillus typhosus, Streptococcus pyogenes,* etc., that after some minutes of contact (exact time not stated) the bacteria could not be cultivated from bouillon, henc [illegible]

Formaldehy [illegible] 1/2000 solution of formaldehyd [illegible] *Bacillus pyocyaneus.* Pottevin[16] fi [illegible] formaldehyd to a liter of boui [illegible] *diphtheriæ, pyocyaneus, typhosu* [illegible] *nes aureus.* Burgess[8] concludes tha [illegible]: 1/30 solution is destructive in one minute, a 1/50 solution in five minutes, and a 1/150 solution in thirty minutes.

Lysol.—Burgess,[8] who included lysol in his experiments on *Bacillus coli,* found that a 1/10 aqueous solution killed it in one minute, a 1/30 solution in five minutes, a 1/250 solution in thirty minutes and a 1/300 solution in one hour.

Boric Acid.—Burgess[8] also found [illegible] on of boric acid was entirely wanting in [illegible] natter how long the exposure. Sternberg[9] c [illegible] from his work on gonococcus and micrococcus of abscess pus.

Phenic Acid.—On streptococci and staphylococci Tarnier et Vignal[6] state that a 3 per cent. aqueous solution of phenic acid is efficient in seventeen minutes, a 2 per cent. solution in eighteen minutes. Chamberland,[17] from his experiments, finds that anthrax bacilli are killed by a forty-eight-hour exposure to a 1/400 solution of phenic acid.

Salicylic Acid.—A 1/240 solution of salicylic acid for three minutes kills putrefactive organisms, according to Cabbot.[10]

Methyl Violet.—Stillings,[18] as his findings from experiments, states that methyl violet is three times as strong as bichlorid in its action on anthrax bacillus and quite as effective as it on st [illegible]

[illegible] e work of Pécholier (1883) on th [illegible] solution on bacteria: that of [illegible] (fumes of tobacco in 1888); and that of Vissalli (fumes of tobacco in 1888); and from added experiments of his own (nicotin in alcohol solution), says in conclusion that "nicotin does not appear gifted with very powerful antiseptic properties for 1/3 of a drop (sufficient to kill a pigeon in a few seconds) does not prevent the development of certain bacteria in 3 c.c. of bouillon." But he concludes from experiments of Tissinari on tubercle bacillus and spirillum of Asiatic cholera, and from his own on bacillus diphtheria that it attenuates the virulence of microbes. Junor[20] reports a case of tetanus cured by local application of infusion of tobacco.

Mercuric Cyanid.—Harrington,[21] using the thread method, found that a 1/1000 solution of mercuric cyanid had to act in thirty minutes to kill *Staphylococcus pyogenes albus,* while a three-hour exposure on *S. aureus* showed no antiseptic effect. Hence it is impractical.

Radium.—It was found by Van Buren,[22] from his experiments on *Bacillus typhosus, Bacillus pyocyaneus* and *Staphylococcus pyogenes aureus,* that radium, acting from eight to thirteen hours, was negative in antiseptic action. Pfeiffer[23] also shows its negative action on *Bacillus typhosus* and the cholera spirillum.

Collargol.—Fortesque-Brickdale[24] states "In solution of 0.5 per cent. and under, collargol has no bactericidal effect on *Streptococcus pyogenes* or *Staphylococcus pyogenes aureus* after a twenty-four-hour exposure to a one-day-old culture. (Plate Method.)" A 1 per cent. solution gave no growth.

Turpentine.—Marx[25] found that it required 1/500 turpentine acting for an hour to hinder the growth of anthrax. Forty minutes was required for *Staphylococcus pyogenes aureus.*

Glycerin.—Copeman,[26] from numerous experiments, fully covered by controls, on *Staphylococcus pyogenes aureus* and *albus, Streptococcus pyogenes, Bacillus anthracis, subtilis, coli communis, pyocyaneus, diphtheriæ,* and *tuberculosis* determines: "(1) No visible development of organisms employed takes place in presence of more than 30 per cent. glycerin in beef peptone broth; (2) all organisms, except coli and subtilis, are killed in less than one minute in the presence of 30 per cent. to 40 per cent. glycerin in the cold."

Potassium Permanganate.—According to Cabbot,[10] a 1/960 aqueous solution of permanganate potassium requires over six minutes to stop putrefaction in a putrefactive solution. Sternberg[9] found that 0.12 per cent. permanganate acting on gonococcus and micrococcus of abscess pus destroyed them.

BIBLIOGRAPHY OF ANTISEPTICS CONTAINING IODIN IN CHEMICAL COMBINATION.

Biniodid of Mercury.—On the *Staphylococcus aureus* and the *Streptococcus,* Tarnier and Vignal[6] have shown that a 1/1000 solution of biniodid of mercury is destructive in nine minutes; a 1/2000 solution in twenty-two minutes. On *Bacillus coli communis,* Burgess[8] states that "biniodid of mercury is by far the strongest and best antiseptic (of the ones he tried), and it is not affected by albumin." In his table he places 1/1000 solution effective in one minute; 1/5000 in five minutes; 1/20000 in ten minutes; 1/80000 in thirty minutes; 1/200000 in one hour.

Lithio-Mercuric Iodid.—Rosenberger,[27] working with lithio-mercuric iodid (34 per cent. mercury, 65 per cent. iodin, 1 per cent. lithium) and using thread method, found that on *Staphylococcus pyogenes aureus,* when threads were moist, 1/1000 solution for thirty seconds killed; 1/5000 for one minute did the same. When threads were dry, 1/1000 for one minute killed; likewise 1/5000 for three minutes. On *Streptococcus pyogenes* (dry threads) 1/1000 for thirty seconds killed; 1/5000 for thirty seconds killed; threads moist, 1/1000 for thirty seconds was effective; 1/5000 required two minutes. On anthrax bacillus 1/1000 solution was necessary for fifteen minutes when threads were dry, and for thirty minutes when moist threads were used. He concludes that this is a much more powerful germicide than the usual mercuric salts.

Iodoform.—The experimental results differ greatly from the clinical. A great deal of experimental work has been done on iodoform. Its action has been tested on various organisms by numerous investigators, and their findings seem to indicate that it possesses no bactericidal properties of any moment. The men who have so determined are Hevn and Rovsing,[28] Riedlin,[29] Baumgarten,[30] Kronacher,[31] Buchner,[32] Kunz,[33] Schnirer,[34] Lubbert,[35] and Tilanus.[36] On the other hand, the work

of Mikulicz,[37] who, on adding iodoform to putrefying liquids, saw putrefaction sometimes stopped and sometimes to continue; that of Maylard,[38] who states that it retards but does not stop the development of anthrax bacillus; and that of Stohegoleff,[39] who found that tubercle bacilli inoculated on 5 per cent. iodoform bouillon were dead in forty-eight hours, seems to indicate that under certain conditions (i. e., where free iodin is eliminated) *it* has a slight antiseptic value.

Clinically, when the iodoform comes in contact with tissues, more free iodin is eliminated, hence the results are much better than experiments would indicate. Its use in tubercular joint injections needs no comment. Vinke[40] reports favorably in two cases of anthrax dressed with iodoform. Sormani[41] found by wounding rabbits and guinea-pigs and injecting them with tetanus bacilli and then treating them with different antiseptics that iodoform was the most active of all, and if applied at once tetanus did not appear. Pryor[42] reports thirty-seven cases of puerperal sepsis with but four deaths treated by packing uterus and widely opened cul-de-sac with iodoform gauze, free iodin being liberated and shown to be present in the urine.

Iodin.—The antiseptic action of iodin was discovered by Davaine[43] in 1873. He found that a 1/12000 solution caused the virulence of anthrax to disappear in thirty minutes. Tarnier and Vignal,[6] in their work on *Staphylococcus pyogenes aureus* and *Streptococcus pyogenes*, found that a 1/1000 solution of potassium iodid required over an hour to kill, a 1/500 solution required fifteen minutes, and a 1/300 solution required eight minutes. White[44] states that he has made a number of tests and observed that "in strength of 1/1000 iodin solution in bouillon no growth of streptococcus occurs. *Staphylococcus aureus* will not grow in strength of 1/5000." Davaine[45] determines that a 1/170000 solution of iodin in contact with anthrax blood for fifty to sixty minutes renders it harmless to inject into guinea-pigs. Sternberg[9] states that a 0.2 per cent. solution destroys gonococcus acting for two hours. Claudius,[1] in his article describing his method of sterilizing catgut by immersing in a solution of one part iodin, one part potassium iodid, and water one hundred parts, for eight days and then transferring to 3 per cent. carbolic acid to rinse off excess of liquid iodin, remarks that from his experiments he has found that a 1 per cent solution kills *Staphylococcus aureus* in three minutes and anthrax in twenty hours. He states further that such a long contact is unnecessary (1/5000 solution kills anthrax spores in a short time).

Clinically, iodin solutions have been used with excellent results in treating anthrax. Sereins[46] reported two cases of anthrax cured by injecting a 1/100 solution around and into pustule. Brochin[47] has also reported two cases successfully treated by the same method. Human actinomycosis has been cured by the daily injection of 2 c.c. of a 10 per cent. iodin solution, as shown by Gaucher.[48]

In concluding the bibliography, it is only necessary to call attention to the great number of different substances employed as antiseptics to show that, as yet, the ideal germicide is a negative quantity.

TECHNIC OF EXPERIMENTAL RESEARCH.

Solution Employed.—A solution of iodin in sodium iodid and water was prepared after the following formula:

Iodin, gms.	2.5
Sodium iodid, gms.	5.5
Aqua (sterilized)	250 *cc.*

This gave a 1/100 solution. From this solution, by aqueous dilution, strengths of 1/200, 1/300, 1/500 and 1/1000 were made. In preparing the mother solution, accuracy was observed in weighing the iodin and sodium iodid. The same care was followed in making dilutions. The glass containers were sterilized.

Asepticity of Solutions.—The varying strengths of solutions were now tested to see whether or not they were, of themselves, sterile. For this purpose the plate method was employed. Three drops of solution were used to inoculate a melted agar tube from which a plate was made. From each strength solution three plates were made. After incubating six days every plate was free from colonies, hence sterile. To confirm results inoculations from the different strengths were made on 6 per cent. glycerin potato and incubated six days. The result was again negative in character.

METHOD OF CONDUCTING EXPERIMENTS.

In conducting the several series of experiments, an effort was made to employ a method which would offer the minimum possibility of error, and, at the same time, approach, as nearly as possible, to the exact relation of bacteria to the body in disease. In other words, the media employed were solid in every case, and the growths on them were allowed to become marked, both in extent and thickness, before beginning experiment. Thus, by the thickness of the growth, the penetrating power of the liquid could be ascertained.

The microörganisms on which the action of the iodin solutions was tried were various enough to permit of definite deductions being made from the results on the antimicrobic action of iodin. Thes[illegible] were: (1) *Bacillus prodigiosus;* (2) [illegible] and spores; (3) *Bacillus tuberculosis;* (4) *Staphylococcus pyogenes aureus;* (5) *Streptococcus pyogenes;* (6) *Blastomyces dermatidis;* (7) *Actinomyces bovis.* On these various growths in the test tubes, the iodin solutions were deposited by means of a sterilized pipette until the surface of the growth was completely covered. After varying periods of time, which are designated in the tables, small loops of growth, thus acted on, were transferred to tubes of sterile media and well inoculated, and then put in incubator and watched for growth. No effort was made to wash the inherent iodin solution from the loops because of the danger of washing away the bacteria. For each time of exposure, four tubes were used, each one being covered by a control tube. It is well to note that the bacterial growths transferred were macroscopic and not microscopic in size.

EXPLANATION OF TABLES.

A, B, C, D=Tubes to which bacteria, acted on by solution, were transferred.

A', B', C', D'=Control tubes inoculated with original healthy bacteria. The figures are based on the use of the unit 1 as the denominator of growth, being purely arbitrary and used for sake of comparison. It refers to the transverse extent of growths from smear and equals about ⅛ of an inch. 2=twice the denominator, 3=three times the denominator and so on.

0=No growth.

?=Slight growth, but not equal to 1-32 inch.

Time=Figures designating days of growth, i. e., Figure 1 means growth on first day or 24 hours after inoculation. Figure 2 means growth on second day or forty-eight hours after inoculation, and so on.

The strength of solution and time of exposure are designated in each table.

ANTHRAX EXPERIMENTS.

The following tables (Group 1) show the results of the experiments with anthrax cultures:

D shows one point, while others are free from growth. On the third day effect still continues, A, C, and D showing points, B, free from growth. This continues the fourth day, A and C showing increase, equaling 1/16 of control growth, B is free from growth, D shows points of growth.

1/300 for *fifteen* minutes shows an inhibitory effect. D shows no growth throughout. On first day the rest show points. On second day there is a very slight increase. On third and fourth days there is a gradual increase, equaling about ¼ control at end.

1/300 for *thirty* minutes exhibits a marked inhibitory effect. On first day there is no growth. The second day points appear on A and D, B is free from growth, and C shows a slight one. On the third and fourth days A, B, and D show no increase in points. C shows a small fractional increase.

CONSIDERATION OF EXPERIMENTAL EVIDENCE ON ANTHRAX.

1/1000 for *fifteen* minutes is negative in action.

1/1000 for *thirty* minutes is negative in action.

1/000 for *sixty* minutes shows an inhibitory effect. On first day A and C give 1/10 of control growth, while B and D show no growth. On second day there is no further development. The third day A shows no further development, B, a slight one, C shows points, and D, no growth. On the fourth day A, B, and C show a further development equaling 1/10 control growth, while D shows points.

1/500 for *fifteen* minutes exhibits an inhibitory effect. The first day A and C give no growth, B one equaling 1/3 control growth, and D, a very slight one. On second day there is a slight increase, A. B, and D showing small fractional growths, C being free from growth. On third and fourth days the increase is progressively more rapid, equaling about ½ control growth on latter day.

1/500 for *thirty* minutes gives a marked inhibitory effect. First day there is no growth. On the second day A and D each show a point, while B and C are free from growth. On the third day B and C still remain without growth, A and D showing a very slight increase. The inhibition is still extremely marked on the fourth day, A and D exhibiting a fair increase in growth, equaling about ¼ control, C remaining free from growth and B showing one point.

1/500 for *sixty* minutes shows a very marked inhibitory effect. On the first day there is no growth. On the second day

1/300 for *sixty* minutes presents a very marked inhibitory effect. B and D show no growth throughout. On the second day a very slight growth appears on C which does not increase on third and fourth days. On third day a very small fractional growth appears on A which increases slightly on fourth day.

1/200 for *fifteen* minutes shows a marked inhibitory effect. A is without growth throughout. On first day there is no growth. On second day B and D show fractional growth which increases rapidly on third and fourth days equaling about ½ control growth. On fourth day a very slight growth appears on C.

1/200 for *thirty* minutes exhibits a very marked inhibitory effect. B and C are without growth throughout. D is without growth until third day when a point appears which does not increase on the fourth day. On the second day a small fractional growth appears on A which increases slowly on remaining days, equaling 1/6 control growth on fourth day.

1/200 for *sixty* minutes shows no growth throughout.

1/100 for *fifteen* minutes shows no growth throughout.

1/100 for *ten* minutes shows no growth throughout.

1/100 for *nine* minutes shows a very marked effect. B, C, and D are without growth throughout. On A there appears on third day a very small fractional growth which increases very slightly on fourth day.

1/100 for *eight* minutes shows a marked inhibitory effect. On first day there is no growth. On second, points appear on A, while B, C and D are free from growth. On third day A and D show fractional growths. B gives a point and C is free from growth. On fourth day A and D increase slowly, equaling about 1/7 control growth. C is without growth and B shows no increase in growth.

---

* All two day-old cultures except in Table 7.

1/100 for *seven* minutes exhibits a marked inhibitory effect. The first day there is no growth. The second day shows points on A, C and D, while B equals 1/3 control growth. On third and fourth days there is a fractional growth which increases slightly, equaling 1/6 control growth.

SUMMARY OF EVIDENCE ON ANTHRAX.

Considering first the strength of solution and time of exposure to same necessary to produce the death of *Bacillus anthracis* plus spores, the evidence shows that a 1/200 solution for one hour or a 1/100 solution for ten minutes procures death. An exposure to a 1/100 solution for less than ten minutes gives a growth. The second consideration or the inhibitory effect, depending as it does on the two factors, i. e., time of exposure and strength of solution, first shows itself after an exposure of the organism to a 1/1000 solution for sixty minutes. The inhibitory effect is marked. The effect is also shown by an exposure of fifteen minutes to a 1/500 solution, but to a lesser degree. As the time of exposure is increased, the inhibitory effect becomes more and more marked. Likewise, as the strength of solution employed is increased, the inhibitory action becomes progressively more powerful. If, after the death point is reached, we decrease the time of exposure, we again come into the sphere of diminishing inhibition.

SUMMARY OF EVIDENCE ON PRODIGIOSUS.

The details of the experiments with prodigiosus cultures are as follows (Group 2):

1/500 for *thirty* minutes shows an inhibitive effect, the experimental growth equaling less than ½ control growth the first day. This effect becomes gradually less on second day. By fourth day control and experimental tubes are practically identical in amount of growth.

1/500 for *sixty* minutes shows an inhibitive effect on A, B, and C, the experimental growth equaling 1/7 control growth the first day. D is negative in action. From second day control and experimental growths are identical in extent.

1/300 for *fifteen* minutes shows an inhibitive effect, the experimental growth equaling 1/10 control growth the first day. This effect becomes gradually less until by the fourth day control and experimental tubes are identical.

1/300 for *thirty* minutes shows an inhibitive effect the first day, the experimental growth equaling 1/12 control growth. This effect becomes gradually less until by fourth day experimental and control growths are practically identical.

1/300 for *sixty* minutes shows a marked inhibitory effect first day, the experimental tubes showing a slight growth. This effect became gradually less until by fourth day experimental tubes show 2/3 of control growth. D, however, does not develop.

1/200 for *fifteen* minutes shows a marked inhibitory effect the first day, A, C, and D being negative, B showing slight growth. Marked inhibitory effect continues the second day when all experimental tubes show very slight growth. On third and fourth days the inhibitory effect still continues markedly, A and D showing no further development, while B and C show slight increase, equaling about 1/5 control growth on fourth day.

1/200 for *thirty* minutes shows a marked inhibitory effect. The first day there is no growth. The second day a slight growth appears on A and B, C and D negative. The third day inhibitive effect still continues, A, C, and D showing slight growth, B, marked increase. On the fourth day there is a gradual increase, the experimental tubes showing about 1/6 of growth on control tubes.

1/200 for *sixty* minutes shows a very marked inhibitory effect, A and D being negative in growth throughout. On second day C shows a very slight growth, B, negative. On third and fourth days B and C show gradually increasing growth equaling 1/3 control growth.

1/100 for *fifteen* minutes gives no growth.

CONSIDERATION OF EXPERIMENTAL EVIDENCE ON PRODIGIOSUS.

1/1000 for *fifteen* minutes is negative in action.

1/1000 for *thirty* minutes is negative in action.

1/1000 for *sixty* minutes shows an inhibitive effect, the experimental growth equaling less than ½ control growth the first day on A and C. This continues relatively the same on remaining days. B and D show no effect.

1/500 for *fifteen* minutes is negative in action.

1/100 for *ten* minutes gives no growth.

1/100 for *nine* minutes gives marked inhibitory effect. On first and second days there is no growth. On third day points appear on A and C, B shows a fractional growth, D is negative. On fourth day B and C show gradual increase, D, negative, and A showing points of growth.

1/100 for *eight* minutes shows an inhibitory effect. First day gives no growth. C is negative throughout. On second day growth appears which gradually increases up to the fourth day when it equals ¼ control growth.

1-100 for *five* minutes shows an inhibitory effect the first day, the experimental growth equaling 1/15 control growth. On the second, third and fourth days, this inhibitory effect becomes rapidly less. On fourth day the experimental growth is 4/5 control growth.

SUMMARY OF EVIDENCE ON PRODIGIOSUS.

In making a summary of the evidence, there are two factors to be considered: (1) The strength of solution and time of exposure to same necessary to produce the death of the microörganism; (2) the inhibitory action of solutions. Considering (1), therefore, we find that a solution less than 1 per cent., acting for an hour, does not destroy *Bacillus prodigiosus*. To cause the death of this organism it is necessary for a 1/100 solution of iodin to act for ten minutes. A shorter period of exposure, i. e., nine, eight and five minutes, gives a growth. On considering (2) it is readily seen that two items have to do with the inhibitory effect. These are, strength of solution and period of exposure. Thus, a solution acting for a certain period of time shows no inhibitory effect, but if the time of exposure is increased, such an effect appears. Conversely, as the strength of the solution is increased, the time of exposure necessary to produce an inhibitory effect becomes less. Bearing these two facts in mind, we find that in this series a slight inhibitory effect is first shown by a 1/1000 solution after an hour's exposure. A 1/500 solution begins to show this effect after thirty minutes' exposure; a 1/300 solution after fifteen minutes. Thus, progressively, as the time of exposure to each strength of solution is lengthened, and the strength of the solution itself is increased, the inhibitory action becomes more marked until the death point of the germ is reached. And, if we try to decrease the time of exposure necessary to produce death, we reach the inhibitory stage again.

TUBERCULOSIS EXPERIMENTS.

Tuberculosis experiments are detailed in Group 3.

* This was watched for a number of days, but no growth appeared on experimental tubes.

CONSIDERATION OF EXPERIMENTAL EVIDENCE ON TUBERCULOSIS.

1/1000 for *fifteen* minutes shows no effect.

1/1000 for *thirty* minutes shows no effect.

1/1000 for *sixty* minutes shows no effect.

1/500 for *fifteen* minutes shows a slight inhibitory effect the first day. This effect becomes less on the second day and disappears on the third day. Experimental tubes and controls are equal on third and fourth days.

1/500 for *thirty* minutes shows an inhibitory effect the first day, A and B showing ½ control growth, while C gives a point and D is free from growth. This inhibitory effect extends slightly into the second day. On third and fourth days A and B equal control growth, C and D slightly less.

1/500 for *sixty* minutes presents an irregular inhibitory effect. The first day A and D are free from growth, C shows a point, and B equals control growth. The second day the inhibitory effect becomes rapidly less, A and C equaling control growths and remaining equal to the same on the third and fourth days while C and D show a rapid increase in growth which, on third and fourth days, does not increase, equaling less than ½ control growth.

1/300 for *fifteen* minutes shows a marked inhibitory effect the first day, there being no growth. On the second day the growth equals ½ control growth. On the third day the inhibitory effect is still slighter and on the fourth day experimental growth is but slightly less than control.

1/300 for *thirty* minutes shows a marked inhibitory effect. The first day there is no growth. A remains without growth throughout. On the second day growth appears which equals less than ½ control growth. On third and fourth days there is a rapid increase in growth. The experimental tubes equal 2/3 control growth on the fourth day.

1/300 for *sixty* minutes presents a marked inhibitory effect. There is no growth the first day. On the second day A, C, and D show a growth equaling 1/3 control growth, while B is free from growth. On third and fourth days this growth increases rather slowly, equaling on the fourth day about 1/3 control growth.

1-200 for *fifteen* minutes shows a marked inhibitory effect. First day there is no growth. On the second day points of growth appear on A and D which on third and fourth days increase scarcely any. On the second day growth appears on B and C which equals about ¼ control growth. This increases slightly on the third and fourth days, equaling about 1/3 control growth.

1/200 for *thirty* minutes shows a very marked inhibitory effect. First day there is no growth. A and D remain free from growth throughout. B is free from growth until fourth day when several points appear. On the second day points appear on C which on the third and fourth days give a slightly increasing fractional growth (1/10 control).

1/200 for *sixty* minutes shows no growth throughout.

1/100 for *fifteen* minutes shows no growth.

1/100 for *ten* minutes shows no growth.

1/100 for *seven* minutes shows no growth.

1/100 for *six* minutes shows a marked inhibitory effect. First day shows no growth. B and C are free from growths throughout. On the second day D shows points and A is sterile. On the third day A gives a point, D a slight fractional growth. On the fourth day A shows two points, D, a slight increase, equaling 1/10 control growth.

1/100 for *five* minutes exhibits a very marked inhibitory effect. On the first day tubes are free from growth. D is free from growth throughout. On the second day A, B and C show points. On the third and fourth days A and C show no increase in growth, while B shows a small fractional one, equaling ⅛ control growth.

SUMMARY OF EVIDENCE ON TUBERCULOSIS.

The evidence shows that to produce the death of the *Bacillus tuberculosis* an exposure to a 1/200 iodin solution for one hour or to a 1/100 solution for seven minutes is necessary. An exposure of less than seven minutes results in a growth. When we come to the consideration of the inhibitory effect we find that a 1/1000 solution for one hour is without effect. Inhibition begins to be shown slightly by a 1/500 solution for fifteen minutes. From this point on, as the period of exposure is increased and as the solution employed becomes of greater strength, the inhibitory effect becomes progressively more and more marked until the death point is reached. Then, if we try to lessen the time of exposure to the necessary strength, we come into the sphere of inhibition which decreases as the exposure decreases.

(To be continued.)

UNILATERAL TRANSITORY PARALYSIS OF THE ABDUCENS.

WITH REPORT OF CASES.*

MEYER WIENER, M.D.

ST. LOUIS.

Paralysis of the sixth nerve occurs with comparative frequency in ophthalmic practice. It may be unilateral or bilateral alone or associated with lesions of other ocular nerves. The causes may be many, including syphilis, congenital or other traumatism, diabetes, central lesions, etc. One etiologic factor, however, has heretofore been questionable and has created considerable controversy; that is, hysteria. Some doubt the existence of a hysterical abducens paralysis, and Möbius[1] denies the existence of hysterical paralysis of the eye muscles at all, and ascribes such paralyses to traumatism; and considers, he states, the "apparent" abducens paralysis to be a spasm of the internal recti. On this point, however, I think we have indisputable proof, as evidenced by cases reported by such authorities as Leber, Parinaud, Nonne and Beselin, Guttman, Duchesne, Roder and Wilbrand.

Within the past twelve months there have come under my observation four cases of unilateral abducens paralysis, which were transitory in character and not associated with paralysis of other ocular nerves or with any tangible disease of any sort.

CASE 1.—Miss Nora Y., aged 9 years, school girl, was brought to the Jewish Hospital Dispensary, June 14, 1904, by her mother, who stated that, three days before, the child had complained of seeing double and the mother then noticed that the child's eyes were crossed. The child had had severe headaches all winter, but the mother was positive that there was no crossing previous to three days before she came.

Examination showed deviation of left eye inward and inability of patient to carry eye outward past median line. The amount of inward deviation of left eye was to the extent of one-third, the cornea being covered by inner canthus. All other ocular movements normal. Pupils normal and react to light and accommodation. V. O. D. = 14/15. V. O. S. = 14/20. Fundus normal. Refraction normal. Fields normal. General appearance good. Color healthy. Mother stated that the child had "brain fever" when 1 year old. Otherwise has been in good health. Mother has four children, all healthy; no miscarriages. No history of syphilis.

Thinking, perhaps, there might possibly be some central trouble or some hysterical signs I might have overlooked, I referred her to the neurolgic clinic. Dr. Schwab could elicit no sign or symptom of hysteria or otherwise. In the face of these facts we still considered the probability of the condition being functional and suggested to the little one that it would get better with medicine. Three-grain doses of sodium bromid were given three times daily. On June 21, patient returned and was able to carry eye outward about 30 degrees. June 30, 1904, patient returned cured.

CASE 2.—Clara A., aged 12, school girl, came to Washington University Eye Dispensary, Sept. 6, 1904. On previous day she noticed blurred vision and diplopia. Parents noticed at same time that eyes crossed. The child was apparently healthy and strong; has had usual diseases of childhood. No history of syphilis or of traumatism. Examination shows deviation of right eye inward and inability to carry right eye outward past median line, in fixing with left eye covered or with both eyes open. All other ocular movements normal. Pupils react to light and accommodation. Had worn glasses for headaches for past three years. V. O. D. 0.5 D. cyl. ax. 90° = 14/15. V. O. S. 0.62 D. cyl. ax. 90° = 14/12. Fundus normal. Refraction +2. No signs of hysteria or other disease.

Patient was treated with three grain doses of sodium bromid and suggestion, and asked to return in a few days. Did not return until Sept. 21, but with complete resolution.

CASE 3.—Maggie S., aged 28, came to office Oct. 15, 1904, with paralysis of left external rectus, which came on suddenly two days before. She stated that about a week before she received a sudden shock by witnessing a street car accident, that she grew suddenly dizzy at the time and nauseated, but felt well after that until two days before coming to office. She is now extremely nervous, but no definite hysterical signs could be elicited. Pupils react to light and accommodation. V. O. D. = 14/300 — 4.5 D. S. ⌢ — 0.5. D. cyl. ax. 120° = 14/25. V. O. S. = 14/25 + 0.5 D. cyl. ax. 90° = 14/15.

Ten grain doses of sodium bromid were given three times daily and October 25 there was complete recovery.

CASE 4.—Minnie V. D., aged 16, came to office May 9, 1905. Two weeks before had tingling of whole left side of head; this lasted one week. When tingling subsided, she noticed that she saw double. She has been troubled with headaches since going to school. She has had usual diseases of childhood; no history of syphilis. Has always been nervous. Present condition: Inability to carry right eye outward past median line, either with left eye closed or with both eyes open. In state of rest, right eye deviates inward. V. O. D. = 14/25. V. O. S. = 14/20. Fundus normal, fields normal. Fauces anesthetic, cornea slightly so. Patient giggles at slightest provocation. Ordered compound syrup of hypophosphites. May 16, 1905, there was no improvement in patient's condition. Ordered sodium bromid 5 grain doses three times daily. Patient did not return until June 17, 1905, when complete resolution had taken place.

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Graefe-Saemisch: Handbuch der Gesammten Augenheilkunde, vol. viii, Chap. xi, p. 11.

Borel[2] reports a case of "true hysterical paralysis of external rectus muscle." The motor disturbances predominated in his case, sometimes in the right and sometimes in the left. In the field of fixation the lateral fixation was 43 degrees inward and 41 degrees outward in the right, and 37 degrees inward and 41 degrees outward in the left eye, which does not indicate a weakness of right rectus muscle, but a failure of all associated movements to right. Again, he states, "at a distance in the median plane homonymous diplopia was observed; nearer, single vision was established, still nearer cross diplopia appeared." These are symptoms of contracture of convergence.

Parinaud[3] says that Samelsohn stated to him that he had seen a case of hysterical paralysis of the sixth pair. Leber[4] and Schwab[5] report cases of bilateral abducens paralysis following typhoid convalescence in the former, there being albuminuria.

Guttman, Cohn, Landenberg, Bernheimer and others report cases of bilateral abducens paralysis in diabetes, which recovered on improvement of general condition. Wilbrand[6] observed abducens paralysis in two nervous women without a deviation inward. In directing the eye straight ahead there was no diplopia. When, however, the eye was directed outward, the eye of the paralyzed side remained fixed while that of the normal side followed the movement of the fingers. In these cases were also present photophobia, blepharospasm and a number of other nervous symptoms.

Röder[7] published, in 1891, a case in which a young 17-year-old girl had a mixed anesthesia, abducens paralysis and mydriasis left. Pupil did not respond to light or accommodation. There was paralysis of accommodation, monocular diplopia and contracted visual field. Patient got well by suggestion.

Freund and Rie[8] report that there occurred, in two cases of cerebral hemiplegia in children, following a new attack of illness (associated with fever and convulsions), a paralysis of the abducens which disappeared in a short while. Schweigger[9] reports a case of contraction of the interni with limitation of movements of the externi. Nonne and Beselin[10] report a 24-year-old patient with "grand hysterie" with hypalgesia, hypasthesia and diminished sense of taste, smell and hearing on left side, with a spastic ptosis and paralysis of left abducens. Patient unable to carry left eye outward past median line. After several attempts, however, by fixing head and manipulating a mirror which patient was looking into, left eye was finally carried outward; but immediately lapsed into former condition.

I am sorry that I did not know of this mirror test at the time I examined my cases, but I do not believe, however, that it would have affected the result.

In conclusion, I maintain that these cases prove that a functional (or hysterical, if you will) paralysis of the abducens does occur; that it may be unilateral or bilateral, and that there need necessarily be no other hysterical signs or symptoms evident, all of which is of the greatest importance from a diagnostic, as well as a prognostic, standpoint.

DISCUSSION.

DR. H. STILLSON, Seattle, Wash., said that he had observed that the ability to rotate the eye outward depends largely on one's individual facility, and that the education of one's external recti is much more difficult than the education of one's internal recti. The examination of eyes with Stevens' instrument often surprises one at the difference in the rotation at different times; a rotation outward at one sitting being very different from that of a subsequent reading. Dr. Stillson thinks, therefore, that some cases mentioned as paresis of the external recti may be put down in the class of hysteria or in the class of cases modified by one's lack of facility, and that in those patients who have recovered rapidly the recovery may be due to the education of the external recti.

PROGRESSIVE AXIAL MYOPIA.

ITS PREVENTION AND CURE BY APPROPRIATE TREATMENT OF THE INTERNAL AND EXTERNAL RECTI MUSCLES; WITH REPORT OF CASES.*

F. S. CROCKER, M.D.
CHICAGO.

It must be admitted that, while the science of ophthalmology, as a whole, has shown a remarkable advance in recent years, our knowledge of the etiology, and particularly the treatment, of progressive myopia is little, if any, greater than it was twenty or thirty years ago.

Various eminent authorities, during recent years, have described what they considered the principal factor in its causation, while others have studied exhaustively the gross and microscopic tissue changes that may be present in the myopic eye; and still others have suggested many ways of bettering the hygienic surroundings and increasing the comfort of the myope; yet no one, to my knowledge, has ever suggested a definite form of treatment for the prevention or cure of this unfortunate condition.

It has been stated by Cohn that 10 per cent. of the blindness of inmates of public institutions in Germany is directly due to an advancing myopia; and Tschering, in Copenhagen, estimates the proportion of myopes in the community at 8 per cent.

In this country, where we possess every facility, and the skill and inclination to do the best refraction work, and in spite of the excellent school hygiene that is nearly everywhere maintained, it is well known to all ophthalmologists that myopia is steadily increasing.

This is more noticeable, of course, in the centers of learning and industry, where a large and increasing necessity for close work is imposing its penalty on all but the more perfect eyes.

It is expedient, then, that we should direct our efforts to the perfection of some means of checking the progress of this dread destroyer of sight and happiness.

To this end I wish to submit a plan of treatment, evolved, in greater part, from my own experience, and employed with a very gratifying degree of success for the past five or six years.

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Briefly, this treatment consists, in addition to the usual routine of correcting refractive errors and vertical imbalance by glasses, and strict attention to the general health, of properly regulated exercise of the internal recti muscles with prisms, and the careful administration of galvanism, locally.

In exceptional cases the above is found inefficient and must be supplemented by operative measures, consisting of tenotomy of the external rectus of one or both eyes.

I am well aware that none of these procedures are new, yet, after a thorough search through a very extensive literature, no mention was found either in special articles or text-books of any one of them having been advised or used in the same manner and for the same purpose as will presently be described.

Both muscle exercise and operative procedures are recommended in extreme cases for relief of the asthenopic symptoms that accompany progressive myopia, and, as a matter of fact, it was while using them for this purpose that I first became aware of their efficiency in preventing the onset, or checking entirely the progress of the disease itself.

As an illustration, the following is quoted from the recently published sixth edition of "Diseases of the Eye," by Edward Nettleship, and it would seem to cover what has been done along these lines:

> Preponderance of the external over the internal recti, insufficiency of convergence, if not cured by partially correcting glasses, may be treated by the division of the external rectus of one or both eyes, but not until after an effort has been made to strengthen convergence by means of properly regulated prismatic exercise.
>
> For this purpose the patient fixes his gaze on a point of light twenty feet away, while the strongest prisms, base out, with which the patient can fuse the light, are placed in a spectacle frame.
>
> After regarding the light a few moments, the eyes being still fixed on it, the prisms are raised and the convergent effort relaxed; after a few moments the prisms are again lowered before the eyes, and this alternate lowering and raising of the prisms, and the consequent stimulation and relaxation of convergence persisted in for five minutes.
>
> These exercises should be repeated three times daily, and the strength of the prisms increased as the patient is found to be able to fuse higher ones. By this procedure the power of adduction is frequently carried to 100 degrees within a few [illegible], with a great relief of the asthenopia.

[illegible] will be noticed in the above quotation—and the same is true of other writers—that, while these or simi[illegible] measures are advised for relief of painful symptoms accompanying myopia, nothing is said regarding their [illegible]ect on the progress of the disease.

It was my custom in the first years of practice to treat all cases of exophoria, whether accompanying myopia or not, by giving the patient prisms of different strengths to use at home, with printed instructions for their guidance, and seeing them at the office only at infrequent intervals, or at the completion of the treatment. By this method gratifying results were obtained in a certain proportion of cases, but there was a considerable number who from one cause or another did not carry the treatment to a successful termination. Either they did not use the prisms understandingly or, not seeing an early and decided improvement in their symptoms, discontinued their use too quickly. Another, and more serious, defect in this method was finally discovered to be that whatever good results were obtained were not in the majority of cases permanent.

One or two of the cases that will be reported at length illustrate this not only as regards the exophoria itself, but in connection with the development of myopia.

DESCRIPTION OF THE TREATMENT.

Realizing that the poor results in some cases were probably due to a lack of thoroughness in applying the treatment, it was decided to keep the patient constantly under observation during its course, and, having in mind the tonic and stimulative properties claimed for the interrupted galvanic current, this was used in connection with the exercises. Better results were soon apparent, and it was found that by continuing the treatment sufficiently long the exophoria was permanently cured in practically all cases, and that without resort to operation. A complete description of the treatment as now used follows:

The patient is given a single square prism, usually 10 degrees, or weaker if necessary, with which to begin the exercises at home. A small candle or gas flame that does not illuminate the surroundings too much is placed on a level with the eyes, and not less than twenty feet away. It is desirable to have the room darkened by lowering the shades, and that it should not contain too many articles that might cause reflections.

It is supposed that distance glasses have been ordered when needed, and with these in place the patient is instructed to produce a crossed diplopia by holding the prism over either eye, base out, and then to attempt to again fuse or bring the two lights into one.

If a prism of the proper strength is given and it is rotated until the two lights are at the same level, little difficulty will be experienced in getting them together.

Since the eye that is covered by the prism is the one that converges in overcoming this artificial diplopia, it is necessary to divide the exercise between the two eyes, say two minutes with the right eye, then two minutes with the left, removing the prism as often as the lights merge into one. This is to be done twice, and, if convenient, three times each day, but not for a longer time than two or three minutes with either eye, and if very noticeable pain is caused the time should be shortened. Each strength of prism is used at least two or three days, or until the lights can be fused very quickly and without apparent effort. When this is accomplished with the 10 degrees, a 3 degrees is added and the two used in the same manner; then the 3 degree is replaced by a 5 degree, and, finally, all three are used, being held together conveniently by a rubber band. When the 18 degrees can be overcome, the 5 degree and 3 degree are replaced by another 10 degree, and the same process may be repeated until a sufficient power of convergence has been obtained, the minimum in the writer's practice being 48 degrees.

The average length of time necessary to reach this point is between three and four months; and during this period the patient should make three or at the least two visits at the office each week to receive local treatments.

The battery or wall plate should be equipped with a milliampere meter, rheostat and automatic interrupter. A double-eye electrode with long handle is attached to the positive pole and the well-moistened sponges applied over the closed upper lids, being held in this position by the patient, while the opposite pole, carrying a moistened sponge, is placed at the nape of the neck by the operator.

The interrupter is so adjusted as to produce about thirty or forty interruptions per minute, and the handle of the rheostat is turned gradually until a faint flash is seen by the patient with each break in the current.

The duration of treatment is five minutes, and it should never cause any discomfort or pain; the slight blurring of vision that may follow its application passes away in a very few moments.

Aside from the intrinsic value of the electricity, its use enables the surgeon to be sure that his instructions regarding the use of the prisms are being fulfilled, and this, in my experience, has been of vital importance.

SUMMARY OF CASES.

Before reporting any cases at length, it may be of interest to present a brief summary of fifty cases taken from the writer's private records, as illustrating with what degree of uniformity certain conditions and symptoms are present. In selecting these cases, none were taken that have been seen for the first time within the past two years, and only those in which the myopia was undoubtedly progressive, this latter being determined by a history of recently failing vision either with or without glasses, and a consideration of the other symptoms. The figures given below are approximate:

Seventy per cent. were females; 30 per cent. males.
Average age at which glasses were first worn, 17 years.
Youngest age at which glasses were first worn, 8 years.
Oldest age at which glasses were first worn, 34 years.
Cases in which no glasses had been worn, 20 per cent.
Cases in which previous glasses were fitted by oculist, 30 per cent.
Cases in which previous glasses were fitted by optician, 50 per cent.
Amount of myopia present, 0.25 to 14.00.
Number of cases requiring [illegible]ations, 3.
Astigmatism present in 90 [illegible]ent. of all eyes, 0.25 to 4.00.
Typical fundus changes in 30 per cent. of all eyes.
Cover test positive in all cases.
Average abduction, 9 degrees.
Average adduction, 10½ degrees.
Highest abduction, 16 degrees, with adduction of 18 degrees.
Highest adduction, 18 degrees (two cases), with abduction 11 degrees and 16 degrees.
Lowest abduction, 4 degrees, with adduction, 8 degrees.
Lowest adduction, 7 degrees, with abduction, 7 degrees.

The following is a record of only the more important symptoms:

Soreness or pain in the eyes themselves, 28 cases.
Some form of headache in all cases.
Panorama headaches and car sickness, 30 cases.
Photophobia in 30 cases.
Nervousness, 20 cases.
Temporary diplopia, 5 cases.

Of course, it is not claimed that every patient not already myopic, who may exhibit any or all of the above conditions, will develop myopia or even show a decrease of hyperopia, if present; nor that every case of myopia (which certainly during its development was progressive) is due to an abnormal converging power, since the general conditions of health and certain occupations may be the determining causes. This is evidenced by a large number of cases that have become stationary, without local treatment of any kind, but simply through change of occupation or improvement in health. On the other hand, the above findings would seem to justify us in promulgating the rule that any case of myopia accompanied by asthenopic symptoms or headache, with deficient converging power and a true exophoria, as shown by the cover test, may be safely classed as progressive, and should receive appropriate treatment, directed not only to a relief of symptoms, but to the abatement of the disease itself.

It must be understood that a number of etiologic factors other than those mentioned may be present in every case, such, for instance, as heredity (the term being used here in the sense that certain inherited anatomic peculiarities may predispose to the acquirement of a myopia); astigmatism, on the importance of which in this disease Ball, in his recently published and very excellent textbook, lays so much stress; and congestion, induced by stooping or other unfavorable positions assumed by the patient, either through habit or from necessity in certain occupations.

We should then, as heretofore, advise our myopic patients as to the proper use of their eyes; also as regards the amount of work and its illumination; and, further, it is of the utmost importance that their general condition of health should receive very careful consideration if we would get the best results from our local treatment.

In a majority of cases reported in this paper, it has been possible to make recent observations, and in none of these has there been an increase of the myopia sufficient to warrant a change of lenses.

The following cases are typical, and are reported at length merely to emphasize certain points in the treatment, and to direct your attention to some of the difficulties of its application:

CASE 1.—Ella D., aged 9 years, Aug. 25, 1898. Never has worn glasses. Could not see writing on blackboard from rear seat. General health good. Has supraorbital and temporal headaches after reading a few minutes. Car sickness marked.

V. L.=20/50. V. R.=20/50. Abduction, 7°; adduction, 12°.

Cover test shows divergence. Refraction with homatropin.

L.+1.25, ax. 90=20/30+R. 1.50, ax. 90=20/30+.

These glasses were ordered, with instructions for patient to return in two weeks.

Nov. 13, 1898: Patient can see much better with glasses, but still has same symptoms, although headaches are not quite as frequent or severe.

Distant vision, 20/30+ both eyes.

Prism exercise was advised and a full set of prisms was given to use at home. Prisms were returned at end of six weeks. She could overcome the diplopia produced by 48°, and headaches had ceased.

Nov. 25, 1899: Patient came in complaining of headaches and failing distant vision.

Vision with glasses: L.=20/50— R.=20/50—.

Refraction with homatropin: L.—1+1.25 ax. 90=20/30+ R.—1+1.50 ax. 90=20/30+.

Abduction, 7°; adduction, 18°; cover test +.

Prism exercise again advised, but not used.

July 28, 1903: Again complains of poor distant vision.

Abduction, 7°; adduction, 16°.

Refraction with homatropin: L.=—1.75—1.25 ax. 180°=20/30+R.—2—1.50 ax. 180=20/30.

Prism exercise and galvanism for ten weeks, with relief of all symptoms.

Sept. 10, 1904: Came in to have broken glass replaced. No symptoms. Abduction, 7°; adduction, 35°. Vision, 20/30+, both eyes.

CASE 2.—Anton R., 12 years old. First seen Oct. 11, 1899. Has noticed failing distant vision for last year and a half. Eyes ache after studying and are frequently inflamed. General health good.

V. L.=20/100. V. R.=20/100+. Abduction, 4°; adduction, 8°. Cover test +. Refraction with atropin: R.—1.25—0.50 ax. 90=20/15— L.—2.25=20/20+.

Muscle exercise was advised, but not taken at this time.

Jan. 27. 1902: Vision with glasses: 20/200, each eye.

Refraction with homatropin: L.—3.50—0.50 ax. 90=20/15. R.—4.50=20/20+.

Myopic crescent marked; no other gross changes. Muscle exercise and galvanism, three months.

Oct. 19, 1904: Last seen. Vision with glasses better than 20/20 in each eye. No symptoms.

CASE 3.—Miss O. R., 15 years old. First seen Nov. 13, 1900. Worn glasses since 8 years of age; fitted by optician, and changed by him twice for stronger ones. Has nearly constant pain in eyes, and frequent supraorbital headaches. Photophobia. Floating spots before both eyes. Mother always nearsighted. Present glasses —10.00 both eyes. V. 4/200, each eye. With glasses, V.=20/200, each eye. Refraction with homatropin: L.—14—1.50 ax. 120=20/40. R.—14—1.50 ax. 90=20/50+; abduction, 10°; adduction, 16°. Cover test +.

Muscle exercise and galvanism were given fourteen weeks, with relief of all asthenopic symptoms.

Dec. 10, 1901: In answer to a request to come in, she wrote as follows: "My eyes are getting along nicely, and I have had no trouble with them this winter."

Case 4.—Mrs. B., 44 years old. Seen Nov. 3, 1899. Worn glasses ten years. Has had them changed frequently by opticians. Has quite severe pain in eyes after a few minutes of sewing, reading or any near work. Nearly constant supraorbital and temporal headaches. Car sickness. Photophobia. She has not been without a headache for any length of time in twenty-five years. Has had three pelvic operations (the exact nature of which was not learned) for the relief of nervousness and headache, but without any benefit, so far as she could see. Is extremely nervous and suffers much with insomnia. Appetite good. Appears perfectly healthy, and weighs nearly 200 pounds.

Present glasses, L.—3.50. R.—4.50.

Vision with glasses, 20/50+, each eye. Abduction, 10°; adduction, 18°. Cover test positive.

Refraction with homatropin: L.—3.00—2.00 ax. 90=20/30+. E.—3.50—2.25 ax. 20=20/20—1 (letter; +1) added to above for reading.

Myopic crescent and thinning of pigment layer, but no other visible fundus changes. Glasses were ordered, No. 2, shade smoke. Prism exercise and galvanism were given at the office three weeks, when patient was compelled to leave for her home in Wisconsin. As she could not come in again for several months, prisms were given for home use. In March, 1900, was using 50° prism, and felt more comfortable in every way, but still complained of the headaches.

A tenotomy of the right external rectus was done in May, 1900.

In June the same operation was performed on L. external rectus.

This relieved entirely the headaches, and up to August, 1903, there was no recurrence, and no necessity for a change of distant glasses.

Case 5.—Hattie K., 12 years old. First seen Jan. 27, 1900. Wearing glasses fitted by optician one year ago, —1.12 both eyes. Has frequent supraorbital headaches, most severe over right eye. Photophobia, conjunctival hyperemia. Has been kept out of school on account of nervousness. Vision L.=20/60. V. R.=20/70+. Abduction, 5°; adduction, 10°. Cover test +.

Refraction with atropin: L.+3.25 ax. 95=20/30+. R. +2.50 ax. 85=20/20—.

Muscle exercise advised and prisms used at home, with relief of headaches for the time being and great lessening of nervousness.

Jan. 18, 1902: Came in complaining of failing distant vision and same symptoms as before. Refraction with homatropin: L.—1.25+3.25 ax. 95=20/30+. R.—2+2.75 ax. 85=20/20—.

Muscle exercise again given, but with the addition of galvanism. All eye symptoms disappeared and school was resumed March 28, 1905. Has had no recurrence of headaches or other symptoms, and only slight nervousness. Vision with glasses, same as three years ago..

Case 6.—Miss M., aged 23 years, seamstress; Oct. 29, 1900, V. L.=6/200. V. R.=10/200.

Is very nervous, otherwise general health good. First glasses fitted by optician one year ago, but not worn recently. Within last few months has been getting very "near-sighted."

After sewing for a short time has "drawing sensation between the eyes and extending to back of head." Eyes ache and are often inflamed. Photophobia; abduction, 12°; adduction, 12°. Cover test +. Refraction with homatropin: L.—10.00—2.50 ax. 180=20/40+. R.=—7.00—300 ax. 180 =20/50—.

Muscle exercise and galvanism relieved eye symptoms, and to a great extent the nervousness.

April 20, 1902, patient was requested to come in. Vision was the same or a trifle better, and no symptoms were complained of.

Patient has never lost any time from her sewing on account of her eyes.

It is reasonable to suppose that without treatment this patient would have developed a still higher degree of myopia, perhaps with the loss of useful vision, as the fundus changes were already quite marked.

I feel justified in basing the following conclusions on the results so far obtained:

1. The most important etiologic factor in a very large number of cases of progressive myopia is an insufficient power of convergence.

2. It is immaterial, in so far as the question of treatment is concerned, whether this inadequate converging power is the result of some anatomic defect in the shape or position of the orbit, or whether it is due to a fault in the insertion or innervation of the extrinsic ocular muscles.

3. In all cases in which destructive fundus changes have not already resulted in too great a loss of vision it is possible to check the progress of the myopia or in the proper sense of the word to effect a cure.

4. Since we have no means of knowing who among our young patients will develop a myopia which may lead to great impairment of vision or perhaps blindness, it should be our constant care in practice, and especially with those of us who have to do with the examination of the eyes of children in the public schools, that, in addition to the correction of refractive errors. the eye muscles should receive due attention, and, when found defective, proper prophylactic treatment instituted or advised.

5. For obvious reasons none but specially qualified legal practitioners of medicine should be allowed to prescribe glasses for, or in any way treat, myopia.

DISCUSSION.

Dr. G. C. Savage, Nashville, Tenn., expressed his inability to explain just why some cases of myopia are progressive, and whether or not the want of converging power predisposes to this increase. He illustrated his understanding of the convergence of myopic eyes on the blackboard. The myopia is, say, 3 degrees. Dr. Savage believes that there is a definite relationship between the tenth and the third (the accommodative and convergence) centers in the brain that the accommodation of myopic eyes is effected not by the conjugate centers, but by the basal centers. Now, without accommodation there may be convergence, but he does not believe that it is volitional if the myopia is 3 diopters or more. Unless there is no necessity for activity of the ciliary muscles in near vision, the tenth conjugate brain center is quiet. But without convergence there would be diplopia. Now this is an abnormal or fusional convergence effected by the right and left third basal centers. That may tend toward increasing the myopia, but how much he is not able to say. The thing to do for these eyes, however, is to correct the myopia in full and to advise that the correction be worn for all distances if the patient is young. When the myopia is corrected for distance and the same is worn for near, the accommodative center becomes active, and the third conjugate center becomes active, and convergence is effected by the volitional center and not by the fusional or basal center. Dr. Savage believes that when there is no need for volitional accommodation there is only fusional convergence.

Dr. F. S. Crocker thought it likely that all agree with Dr. Savage that it is the proper thing to correct the myopia fully in nearly all cases, but Dr. Crocker did not think that that has anything to do with the arrest of progress of the myopia. Fifty per cent. in his experience have been fitted by opticians, and he said it is a common experience to find that the optician overcorrects myopia, yet it is progressive.

THE NON-TOXIC AMBLYOPIAS.*

T. W. MOORE, M.D.
HUNTINGTON, W. VA.

I believe that the non-toxic amblyopias can be better studied if considered under three heads: 1. Those cases of amblyopia exanopsia due, as is usually believed, to the inability to use corresponding areas of the retina at the same time. This may be due to high refractive errors, to improper balance of the extraocular muscles, or to a non-development of the fusion center *in the cerebrum.*

2. That large group characterized by irregularly contracted but constant fields, impaired vision with careful tests, often only perceiving moving objects, but never interfering with locomotion or similar acts, frequently monocular diplopia, etc., etc., and known as the hysterical amblyopias.

3. That similar but sufficiently different group to justify their place in a separate class, characterized by impaired vision, contracted fields for white and colors always retaining their normal relationships, i. e., no reversal, and being proportionate to the visual acuity; these cases are usually designated as anesthesia of the retina.

Then, lastly, we have the group due to traumatism, often where there is evidence of pathologic changes of the fundus in the form of an old rupture of the choroid or retinal hemorrhage that has left the parts of the fundus uninvolved healthy, *but vision has not returned.* These cases are closely allied to the group just preceding, differing only in their etiology and the limited results that can be brought about by treatment.

The diagnosis of the cases of amblyopia exanopsia is not usually difficult, the defective vision, the apparently normal fundus, the one eye squinting frequently, and the high refractive error in one or both eyes usually renders the case clear from the first. It is difficult to decide whether the squint is due to the defect in vision or the reverse, but in a large proportion of cases the former is doubtless the case.

What shall we do in these cases? I do not believe, when we prescribe lenses and turn the patient away without any other treatment or advice regarding the amblyopic eye, that we have done our full duty, providing the patient is under 40 years of age. Of course, the younger our patient the greater the chances of bringing about permanent improvement, but cases like the one recently reported by St. John Roosa, where a man of 46 lost his seeing eye, and after five years the vision in his amblyopic eye had improved from 20/200 to 20/30 with an appropriate lens, the near vision improving much more rapidly than that for distance, and the several cases of this kind found in ophthalmic literature encourages us to try to improve these eyes.

I have tried numerous devices, such as covering the good eye for one or two hours daily, the amblyoscope, etc., but have found the convex glass cure, as recommended by Fronmuller in 1857, the most satisfactory. I can not do better than to quote his directions in full:

> In this sort of exercise, printed types are best suited as visual objects, since in them there is a change from letter to letter, and, therefore, the attention must be directed uninterruptedly to the object, and mistakes, which have slipped into the estimate of what is perceived, appear immediately by the context, and therefore, invite correction. These printed types must, of course, be well illuminated, and must moreover, be projected on the retina under a large visual angle, in default whereof they appear, even in slight torpor of the light-perceptive apparatus, as images which can not be deciphered. They must, therefore, be chosen large, and brought near the eye. But in order to see as clearly as possible at short distances, convex glasses are usually needed, as the amblyopia exanopsia is, as a rule, accompanied by weakness of the apparatus of accommodation. Convex glasses are, moreover, under all circumstances very useful, as, by an apparent brightness of the retinal images, they increase the distinctness of the perceptions and facilitate the choice of test-types. It is, therefore, the custom to employ them in all cases, at least at first, and to distinguish the exercise in general with the name of treatment by convex glasses. The weakest convex glass must here be first ascertained, which enables the affected eye, the other one being closed, to decipher larger printed types (Jaeger, No. 12-20) at a distance of from 8-12 inches. With this glass the patient must now undertake, two or three times a day, exercise in reading, at first for five minutes, but gradually increasing the time, but should never push the attempt so far as to excite symptoms of fatigue, pain, congestion, or inflammation. On the whole this method of treatment, particularly in the higher degrees of amblyopia, demands in many cases great patience and perseverance, as it is often very long before any perceptible effects make their appearance. Finally, however, the power of vision often increases in favorable cases in very rapid progression. It is then time to pass to weaker glasses, and by lengthening the periods of exercise to rise to smaller and smaller test-types. Sometimes the progress is all at once arrested, and the power of vision does not improve, in spite of all that can be done. We should not then lose courage! for all at once it again advances, and we finally are able to employ glasses which are weaker by many numbers, or we may even reach a point where glasses are found to be superfluous. If the eye has become so far cured that ordinary printed type may be read fluently with weak convex glasses or without any, the reading exercise must still be continued for a time, in order to confirm the cure, and prevent relapses.

In some of these cases my results have been surprisingly good, in others less so, but in all cases where I could command the co-operation of the patient there has been some improvement.

With the hysterical amblyopias the diagnosis is, as a rule, not difficult, the concentrically narrowed field of vision with reversal for colors being characteristic. There are diseases in which we have this contraction, such as atrophy of the optic nerve and glaucoma, but without the reversal for colors. It may seem superfluous to call attention to this, but in their incipiency it often taxes the resources of the most skillful to say whether a disc is normal or not, and it is here that the exact perimetric measurements give us valuable aid, for in the nervous types the degree of contraction is practically equal in all meridians, whereas in the diseases mentioned it usually advances, with irregularly reentering angles toward the point of fixation, as is so tersely pointed out by Swanzy.

Parinaud says:

> This concentric contraction of the field is also found in some cases of cerebral tumor and without neuritis, or it may result from intracranial pressure associated with certain forms of extensive cerebral meningitis; also it is not infrequently observed in epilepsy, and in this latter disease the diagnosis is often difficult, especially where there is temporary amaurosis, which is undoubtedly a manifestation of epilepsy, but unaccompanied by convulsive attacks. This is the same condition that Feré reports as characteristic of the amblyopia following epileptic attacks, i. e., the contracted field not accompanied by dyschromatopsia, especially the peculiar inversion of the color field.

The varying, never constant symptoms usually manifested by all hysterical subjects should be remembered, especially the symptoms of the hysterical amblyope, such as the contracted field with reversal for colors, the varying degrees of diminished vision, frequently monocular, the failure of accommodation, the scotoma and hemiopia, and the less frequent photophobia, blepharospasm, ptosis, etc.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The treatment consists in building up the patient's general health, by cold baths, plenty of outdoor exercise, tonics, electricity, the correction of any error of refraction, etc. These cases all recover, but some of them tax our skill and patience to the uttermost.

Then, we have those cases known as anesthesia of the retina, of which etiologically we have two classes, those of unknown cause and those due to traumatism. Charcot and Leber have asserted that these cases are of a hysterical character and place the seat of the disease in the brain and not in the retina, but do not the results of treatment prove that the trouble is in the retina?

These cases, as recently pointed out by Fox, are characterized by partial loss of vision for near and distance, contracted fields with retention of the normal color relationship, i. e., no reversal. The fundus is normal and refractive errors usually very slight. This usually comes on suddenly, but there may be a gradual loss of vision, and this is not accompanied by photophobia, blepharospasm, anesthesia of the cornea, etc., as the hysterical cases so often are. The traumatic cases are seen after the patient has recovered from an injury, such as a blow on the eye from a fist, or a cork from a bottle, etc. There is usually considerable amblyopia, with concentric contraction of the field, which may continue for a long time, while the ophthalmoscopic appearance may be normal; or there may be a lesion, such as rupture of the choroid, but the lack of vision is much greater than the ophthalmoscopic lesion leads us to expect.

I probably can illustrate better by describing a case recently treated:

Nellie F. was shot with a rifle ball over the right eye, October 8; two weeks later the ball could be felt on the crest of orbit at junction of outer and middle thirds. Small pigment spots could be seen in peripheral portion of retina and a small horseshoe shaped line of pigment about as large as the disc and on the nasal side of same. November 2 she counted fingers at 5½ feet; on January 7, fingers at 3 feet; after using high frequency current five minutes, at 5½ feet; January 11, fingers at 8 feet; after high frequency, 12 feet; January 14, fingers at 18 feet; after high frequency, 20/200. This continued until March 1, vision having reached 15/120, but could not be improved beyond this.

I do not think that there is any doubt that there existed anesthesia of the retina due to traumatism. Of course, there was, in addition, a rupture of the choroid, as shown by the ophthalmoscope, which accounts for the limited improvement.

The treatment of these anesthesias is electricity, which cures all the non-traumatic cases and benefits them; and, while the galvanic current seems to meet all the requirements, the faradic and high frequency are equally as efficient, and I think the latter is the most useful. The electrode should be applied over the closed lids, when the unipolar current is used. The bipolar is equally efficient. In applying the latter the patient can hold the other electrode in his hand. With the reflex amblyopias due to irritation of branches of the fifth nerve and other causes, such as intestinal parasites, I have had no experience.

DISCUSSION.

Dr. G. C. Savage, Nashville, stated that within the past two years he has had under his care a patient who goes to prove that the amblyopia of squint is mental and not ocular. The patient was a railroad man, but how he got into the service Dr. Savage does not know. He had one blind eye and one good one, the blind eye turning in toward the nose. He was on a train approaching Nashville, going up a steep grade, when a cinder penetrated the cornea and lens, producing a traumatic cataract in the good eye. The next morning he was taken to Dr. Savage's office almost entirely blind. The lens grew more and more opaque. In the meantime he had only the other eye to depend on, and it swung straight while the injured eye turned in toward the nose. In less than ten days the vision arose from 10/200 to 20/30. Every one of these cases should impress on physicians the fact that the blindness of the squinting eye is mental and not ocular. The first thing that should be done is to correct the muscle error, not by complete tenotomy, but by partial tenotomy and advancement, then the physician will never be confronted later by that patient with one eye looking in the opposite direction. The patients should be treated by operative measures first, and then the vision in the blind eye should be developed. The amblyoscope is, of course, a splendid instrument for that purpose. Atropin may be used in the good eye so that near vision with it will be impossible. Dr. Savage emphasized the necessity for first correcting the focal and muscle errors, thus making it possible to have binocular single vision, and then beginning training the blind eye. Dr. Savage mentioned a case of hysterical amblyopia. About six years ago a woman became totally blind in both eyes. Her actions led Dr. Savage to believe that the condition was hysterical. Pupillary reaction was gone. He told her with great positiveness that she would recover, that she would not be long in recovering, and that she would recover just as suddenly as she had lost her sight. One evening, when she was brought in by her sister, he said, "If you are not seeing by morning I am going to have you hypnotized." That night he received a telephone message to come to the boarding house where she was stopping. The patient was sitting there happy and radiant, and seeing as well as she had ever seen in her life.

Dr. Dudley S. Reynolds, Louisville, said that a very common class of cases which, if not entirely ignored, are at least accorded insufficient attention are those cases of injury due to concussion, railroad accidents, trauma amblyopias. In these cases there is gradually increasing peripheral limitation of the field of vision and at the same time there is gradual reduction of the acuity of perception. He has known of cases of this kind in which no recognition of the nature of the trouble occurred for a year or for a year and a half after the accident, when it was noticed by the patient that the field of vision was narrower, or that acuity of perception was obtunded. Dr. Reynolds disagreed with Dr. Moore that no ophthalmologic indications are present. While these may be slight, they are nevertheless distinct. He is sure, too, that amblyopias that are non-toxic traumatic amblyopias, are not benefited by any form of treatment. They are very common and in some instances progressive, leading to entire or nearly entire blindness.

Dr. William Campbell Posey, Philadelphia, spoke in favor of the amblyoscope in developing vision in the squinting eyes of children. He has used it a great deal in the last few years and has found it a very valuable means of re-establishing binocular vision. In order that the treatment with this instrument should be efficacious, it is necessary that it should be employed before the child has arrived at the age of six years; if it be postponed until after that age the results will be disappointing. It should be remembered that treatment for the correction of squint can not be begun too early, and even at the age of one year, if the squint has been diagnosed, atropin should be used in the good eye, with a view to blurring its vision and inviting the patient to use the squinting eye. Some clinicians instill atrophin into both eyes. While when used in this way the spasm of accommodation may be overcome and the relationship between accommodation and convergence re-established, the vision in the squinting eye is not improved, and the chief value which may be gained from the employment of the drug is not attained. At the age of 2 years the proper glasses should be put on the child, the lenses being selected by retinoscopy. Mr. Worth orders glasses at even a younger age, but Dr. Posey thinks that as the frames must be bound on the head by tapes, there is some danger in such young subjects, in interfering with the proper development of the bones of the face, and possibly with the eyes themselves, from pressure. The amblyoscope may be used at the age of 3 or 4 years, and if employed persistently, the results obtained are very gratifying.

Dr. S. D. Risley, Philadelphia, declared that, in the management of squint occurring in early childhood we should not be unmindful of the somewhat limited group of cases in which the convergence is not due to the usual error of refraction, but is associated with, and probably caused by a central blind spot. It is not possible to demonstrate the presence of this in very young children, but its existence should be suspected when the well-known methods of treatment fail to correct the deviation. Dr. Risley has a number of times been able to verify this diagnosis after the child was old enough to permit a demonstration of a macular scotoma. He agreed with Dr. Posey and Dr. Moore that all cases of strabismus, when the deviation is due to refraction error, should be corrected by glasses very early in life. When seen early and when the correction is accurately made, there need be but little difficulty in securing binocular vision, even without the aid of the amblyoscope. Dr. Risley expressed surprise to hear Dr. Savage give credit to Dr. Worth for devising the use of atropin in the good, or fixing eye, to compel the use of the deviating eye. Dr. Risley has used the drug in this manner during his entire experience and the method did not originate with him so far as he knows. He called attention to the fact that in amblyopia of the deviating eye impaired vision may be due to the peculiar error of refraction, or to commencing disease in the macula, and the apparent amblyopia disappear as soon as these are corrected. Which eye shall deviate may be determined by the greater impairment of vision produced by the higher refraction error or by asymmetrical corneal meridians, for example; or it may be by a faulty attachment of one or more muscles to the globe, a condition which is often foreshadowed by certain deformities in the skull which lead to abnormalities in the shape of the orbit. It is obvious, therefore, that in the study of strabismus or other defects of ocular balance each case must be considered separately. We can formulate no law by which all cases are to be compared. We can not hope to secure by Worth's amblyoscope, or by any other instrument, binocular single vision until the refraction error has been accurately corrected, and not then in the presence of macular scotomata, or in cases where the anatomic relation of the muscles is at fault. In these last named cases the only hope is in prudent surgical interference.

Dr. Leartus Connor, Detroit, stated that there is another class of cases, perhaps somewhat rare, in which nothing appears to account for the amblyopia occurring after previously good sight other than malnutrition, presumably of the retina. A year ago last October a man over 60 years old came to Dr. Connor with a history of good health previous to the past four months, when he had been gradually losing sight, until his vision was reduced to 6/200 in one eye and 8/200 in the other. The ophthalmoscopic image showed nothing except that the retinal artery was distinctly smaller in either eye than normal. The field of vision was very decidedly restricted. The refractive errors had been perfectly corrected. The only thing that constitutionally seemed to have any bearing on the case was a persistent indigestion. Dr. Connor employed vibratory massage on the eyeball and within a month vision was 20/200, and at the end of three months the patient could read Jaeger No. 1 and had 20/20 vision for distance. The only two factors observed in the case were the diminished blood supply to the retina and the poor digestion. The case puzzled Dr. Connor at the time and he is not absolutely clear about it yet, but the patient's improvement certainly followed the improved nutrition of the retina. Putting this observation with others. Dr. Connor is inclined to think that in not a few cases there is impaired digestion and interference with nutrient processes which tend to diminish the power of the special senses.

Dr. T. W. Moore said that from Dr. Savage's remarks he inferred that Dr. Savage has been able to produce binocular vision in these cases in which the patients were over 6 years of age. Dr. Moore has tried it in a few cases, but has absolutely failed. He thinks that has been the usual result. Recently he has only tried to increase the vision in the blind eye in patients over 6.

EXPERIMENTAL AND CLINICAL EVIDENCE OF DYNAMIC (SPASTIC) ASTIGMATISM.*

F. B. EATON, M.D.
SAN FRANCISCO.

Dynamic astigmatism may be defined as a condition of the eye due to dynamic changes in its media which prevent homocentric rays from being brought to a focus on the retina.

That such dynamic changes occur there is a preponderance of evidence and opinion on the part of Javal,[1] Georges Martin,[2] Landolt,[3] Dobrowolsky,[4] Oliver,[5] Noyes[6] Panas[7] and others. Among authors who deny this condition I note only Bull[8] and Tscherning.[9] The authors in the first group, while stating briefly a belief in the existence of the condition, are nearly all silent as to its clinical significance, implying, apparently, indifference to it in this respect.

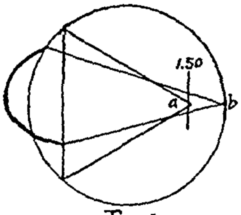

Fig 1

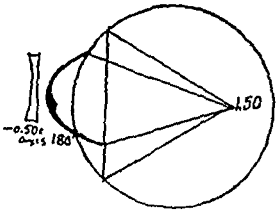

Fig. 2

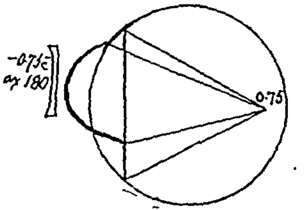

Fig 3

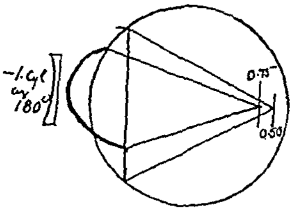

Fig 4

As far as I know, no one has gone so carefully and exhaustively into the subjective phenomena pointing to dynamic astigmatic contractions as Georges Martin[10] of Bordeaux, who published a series of papers entitled "Etudes sur les Contractions Astigmatiques du Muscle Ciliaire," which were afterward collected and published in a small volume of about 200 pages. He records in detail about 150 cases in 300 eyes, and the volume is dedicated to Javal and Schiotz. In it the subject is presented with the utmost minuteness of observation and record in nearly every aspect in which it is possible to view it. When Martin's papers appeared, seventeen years ago, they attracted my attention because I observed facts clinically which apparently corroborated his. I was not convinced, however, though again and again, in the years following, in doing refraction work, I was reminded of the subject by phenomena similar to Martin's records.

[10] Annales d'Oculistique, 1886-1887.

It was not until 1902 that I began systematically to record these observations, and I was startled to find how accurate were his records when duly analyzed. In comparing his findings with mine, I found a difficulty owing to his peculiar method of marking his astigmatic dial and his trial-frame cells, and probably this has proved an obstacle to others in this country, since we follow the mathematical protractor.

To save time in recording cases, Martin adopted certain signs of abbreviation. To indicate that the dial lines appear equal, he wrote the sign ⊙ which exists in typography, especially in works on botany. If a line on the dial appeared clearer than the rest, he wrote the sign ○, writing by the side of it the number of degrees of said line. The principal portion of Martin's treatise deals with three forms of dynamic contractions: *Contractions rénitentes,* which I translate tonic contractions; *contractions élastiques,* which I translate clonic contractions, and *contractions résistantes,* which, of course, are the same in English. About half of the treatise deals with what Martin terms "associated partial contractions," or astigmatic contractions in an astigmatic and "active" eye, producing, by the law of associated movements (Vulpian), a functional astigmatism in the other, "passive" and non-astigmatic eye.

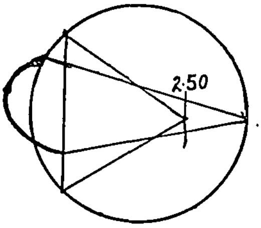

Fig. 5.

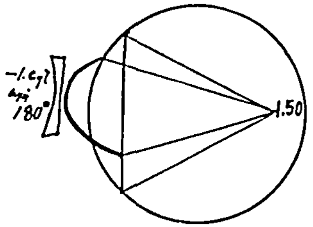

Fig. 6.

This paper permits me only to outline Martin's clinical methods and findings, to adduce some of my own, and to describe briefly certain subjective and objective investigations of my own and other eyes, which apparently prove dynamic astigmatism caused by the accommodative apparatus on the one hand, and by the extraocular muscles on the other.

I present first some simpler examples of Martin's cases, using the notation of our own charts and trial frame, but premising that I do not assume the correctness, as he did, of Javal's dictum of 1887, that the corneal astigmatism constitutes, almost without exception, the total astigmatism. I therefore select some of the cases in which atropin was used three or more days.

Miss ——, aged 17. Intense chorionic blepharitis. Javal (ophthalmometer), 1.50 D. to rule. O. D. V. 1/1?? Em. ⊙ w.+ 0.50s. ⊙ 90.
w.—0.50c. ax. 180° ⊙ 1/1?
w.—0.75c. ax. 180° ⊙ 1/1
w.—1.00c. ax. 180° ○ 180 1/1?
Under atropin, w.—1.50c. ax. 180° ⊙ 1/1

Martin's tests may be graphically analyzed thus:

Under atropin the course of the rays is as in *Fig. 1, a* being the position of the focal line of those passing through the vertical, and *b* those through the horizontal meridian. Fig. 2 represents their path before the use of atropin with—0.50c. ax. 180° before the eye. Here the —0.50c. ax. 180° has thrown the vertical meridian rays back to that extent (myopia 1.00 D.) where, by a dynamic astigmatic contraction affecting the horizontal meridian rays, all rays meet at —1.00 D., the result being a myopia of 1.00 D. with equalized appearance of the astigmatic chart (⊙), but vision of 1/1?

Fig. 3 shows the path of the rays with a —0.75c. ax. 180° before the eye.

Now, the vertical meridian rays are thrown back to that extent, but the contraction affecting the horizontal meridian rays has relaxed; i. e., according to Martin the contraction is elastic (clonic); for, at the very first test, with no lens before the eye the chart lines were equal, and the myopia 1.50 D., the contraction has relaxed 1.50 D. —0.75 D. = 0.75 D., and the result is a myopia of 0.75 D. with the chart lines equalized (⊙) and V. = 1/1. Fig. 4 shows the path with —1.00c. ax. 180° before the eye. Here the vertical meridian rays have been thrown back so that in that meridian there remains only 0.50 D. of myopia. But now the contraction affecting the horizontal meridian rays does not relax, the rays still meet at 0.75; hence the horizontal line on the chart becomes the clearest. According to Martin, there is, therefore, a tonic (rénitente) contraction of 0.75 D. affecting the horizontal meridian. The result is astigmatism and V. lessened to 1/1.

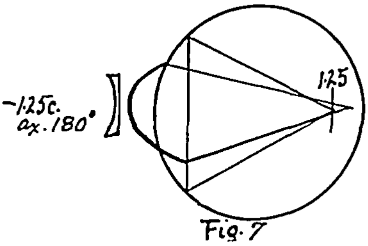

Fig. 7

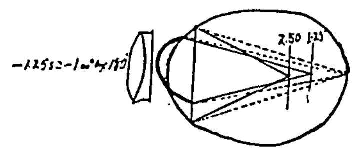

Fig. 8.

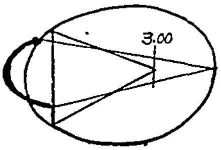

Fig 9.

A more striking case of Martin illustrates a much higher degree of tonic contraction:

L., aged 9. Corneal astigmatism 2.50 D. to rule.
Without atropin O. D. V.=2/5? ○90; w.— ax. 180°. ⊙ V. 1/2.
Without atropin O. D. V.; w.—1.25c. a V.
Without atropin O. D. V.; w.—1.25s.⊂-
V. 2/3.

Fig. 5 shows the path he rays und

producing ⊙ but leaving .50 D.

Fig. 7 shows the path th —
180 degrees before the e er ha

the vertical meridian lines back to the focal point, 1.25 D., but the contraction affecting the horizontal meridian lines has relaxed (clonic), and the vertical line of the chart is the clearest.

Lastly, with —1.25s.⊃—1.00c. ax. 180 degrees, the chart lines are equalized and vision becomes 2/3, equal to the vision under atropin with full correction by —2.50c. ax. 180 degrees. The contractions of the horizontal meridian thus neutralized are shown in Fig. 8; the black lines indicate a myopia in the vertical meridian of 2.50 D., and the tonic contraction affecting the horizontal meridian rays, of 1.25 D. The dotted lines indicate both the effect of the cylinder on the vertical meridian rays, and the disappearance of all contraction in the horizontal meridian under atropin.

The highest degree of dynamic astigmatism I have seen was in the *following case:*

W., aged 41. April 4, 1904, complained of defective vision and severe headaches. He has never worn glasses. He has been exposed late at night to electric light. Eyes are very irritable.

Examination.—V. O. C. = 21/29 ⊙$_{oo}$. Neither minus or plus cylinders or spheres improved vision. Hyoscin hydrobromate .25 per cent. for 48 hours.

V. O. D. w.—3.00 cyl. ax. 5°=21/10???, ⊙

V. O. S. w.—3.00 cyl. ax. 175°=21/16, ⊙

The path of the rays with cycloplegic in O. D. is shown in Fig. 9.

Since both spheros and cylinders were refused before the use of the cycloplegic, there was a tonic dynamic contraction affecting the 5° meridian rays of 3 D.

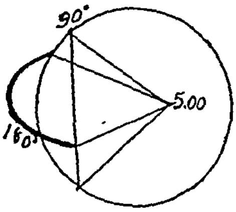

Fig. 10

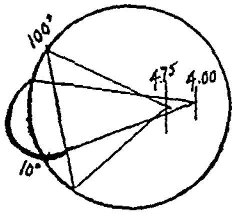

Fig. 11.

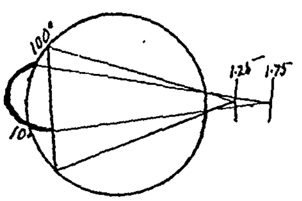

Fig. 12.

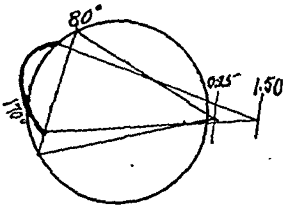

Fig 13.

Among a large number of my own cases of the condition under consideration I select two examined after twelve and eleven years, respectively, as of value in showing how persistent are dynamic contractions, and how they may mask the true static refraction.

S. S., girl, aged 17, was seen first in 1892. Subjective tests then gave myopia corrected by: O. D.—5.00 sph. ⊙ O. S.—2.25 sph. ⊙

In 1895, aged 20 by skiascopy: O. D.—5.00 sph. O. S.—2.25 sph.

January, 1895: Atropin 1 per cent. for four days. Skiascopy; O. D.—4.50 sph.⊃—0.25c ax. 90°! O. S.—2.25 sph.

Trial case: O. D. V. w.—5.00s=20/20?? ⊙. O. S. V. w.—2.75s=20/20 ⊙

In 1904, nine years later, aged 29, Javal: O. D. 10± 1.37 D. O. S. 150° ± 0.50D.

O. D. V. w.—4.00 sph.⊃—0.75 cyl. ax 10°=21-19???⊙

O. S. V. w.—2.50 sph.=21/19, 21/13???

The path of the rays in O. D. in 1895 is shown in Fig. 10; in 1904, in Fig. 11.

Comparison of cuts shows a disappearance in 1904 of a tonic contraction affecting the meridian of 10 degrees, of 1.00 D. which atropin had not uncovered.

N. L., girl, aged 10, 1894. Asthenopia. Atropin 1 per cent. instilled for one week:

O. D. V. w+1.75s.⊃—0.50 cyl. ax. 10°=6/5,⊙

O. S. V. w.+1.75s.=6/5.⊙

A year later, skiascopy gave the same refraction in each eye, and Javal O. S. 1.25 to rule. Fig. 12 shows the path of the rays under atropin in 1894, in O. D.

January, 1905, aged 21. She has worn, for near only, a pair of +1.25 cylinders, axes 90°; has done much drawing. O. S. mucopurulent conjunctivitis.

Trial case: O. D. V. w.+1.50s.⊃—1.25c. ax. 170°=21/16, ⊙ O. S. V. w.+1.50s.⊃—1.25c. ax. 10°=21/16. ⊙

The path of the rays in O.D. in 1905 is shown in Fig. 13, which, when compared with Fig. 12, shows that in 1905 there was a contraction in the O. D., changing the principal meridians from 10 degrees and 100 degrees to 170 degrees and 80 degrees. Also that there was a general contraction of 0.25 D., and a tonic dynamic contraction in the meridian of greatest refraction of 0.75 D. It might seem well that a cylinder of 1.25 D. was accepted in 1905, as against one of only 0.50 D. accepted under long use of atropin in 1894. But the discomfort and irritation of the eyes and the conjunctivitis favor the original atropin correction. How often, after careful correction of compound hyperopic astigmatism, we are forced to increase the sphere, and to decrease the strength of the cylinder.

That Javal was himself the subject of a high degree of astigmatism against the rule is, I think, perhaps fairly well known. That his eyes corrected this, in his opinion, is not, I think, so generally known. At the International Medical Congress at London in 1881 he cited these facts, stating that when 16 years of age he saw the stars as perfectly round points when he made an effort difficult to maintain. When 24 his manifest astigmatism was about 2.00 D., and at 44 it was 2.50 D. Javal recorded one of his cases, M. L., whose corneal astigmatism at the age of 34 (1865) was 6.50 D., and the subjective error but 4 D., indicating to Javal a dynamic contraction of 2.50 D. In 1869 the subjective astigmatism was 6 D., and in 1881 7.50 D.

Samuel Theobald[11] in 1885 cited three similar cases in hyperopes observed during twelve and sixteen years in which the astigmatism increased from 1 to 3 D.[10]

FREQUENCY OF THE CONDITION.

Dynamic astigmatism, in my own experience, exists very frequently, and nearly always in tired, irritable eyes which are affected with organic (corneal or lenticular) astigmatism. It is often overlooked simply because it is so often thought that the ciliary muscle and the convergence excess have been paralyzed completely by some weak or strong cycloplegic.

We say: "The tongue can no man tame." Who can tell when he has subdued the ciliary muscle? There are times when no man can tame it; nor are such times infrequent. I have tested hyperopic eyes which accepted no cylinders, though the corneal astigmatism was 1.50 D., yet by patient, so-called "fogging" for days nearly this whole amount became manifested, together with a higher degree of hyperopia.

---

[11] Amer. Jour. Ophth., July, 1885.

EFFECTS OF AGE, STATE OF HEALTH AND TEMPERAMENT.

It has been generally noted that dynamic astigmatism predominates in youth and disappears at the age of 40 or 50. As to disappearance at the presbyopic age, Javal and Martin note numbers of cases as exceptions, and I have seen undoubted ones between 50 and 65, and once in a woman of 73. General debility, the asthenic state, etc., prevent dynamic contractions, which, in the young, reappear when the patient recovers normal vigor. Martin exhibits a conservatism that points a lesson to some extremists of this day who would disenthrone migraine as a distinctly nervous disease. He states: "The contraction alone is incapable of producing neuralgic crises; it is necessary that it occur in a subject constitutionally affected with a diathesis (arthritism, or herpetism)."

MECHANISM OF DYNAMIC ASTIGMATISM.

This is not easily explained, for there is even yet no universal agreement as to the mechanism of accommodation. Martin[2] disavows any intention of asserting that certain fibers of the ciliary muscle contract, but only that the partial contraction in question causes a convexity of the lens in a certain meridian. Dr. Chas. A. Oliver[12] remarks that during astigmatic tests "it will at times be found not only that the amounts of the defect change when the examinations are made with the two eyes simultaneously, but that the relative angles of the two principal meridians likewise change. This is possibly to be accounted for in a measure by the action of the extraocular muscles in producing, both directly and indirectly, different degrees of tension on the eyeballs during their combined functioning."

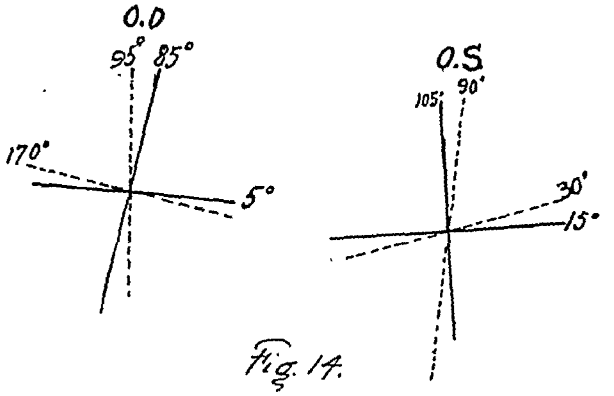

Fig. 14.

Priestly Smith[13] cites a case in which in one eye there was total paralysis of the externus and internus, the other muscles being intact. The patient complained that vision of this eye was impaired. The ophthalmoscope showed no change in the fundus or media, but skiascopy showed 1.00 D. of astigmatism in the vertical meridian corrected with a —1.00 D. cylinder axis horizontal to normal vision. On recovery from the paralysis, all traces of astigmatism vanished.

This brings me to some investigations of my own, made on my own eyes and on those of others, in the endeavor to estimate the relative importance of the action of the accommodative apparatus on the one hand and of the extraocular muscles on the other, in producing dynamic astigmatism. These comprise two kinds of experiments:

1. The objective examination of the corneal curvature by the ophthalmometer with the eyes at rest, and the changes in curvature and direction of the meridians due to more or less convergence and accommodation.

2. Tests with the astigmatic chart at 20 feet in a static state of rest in the primary position, and the changes in the meridians and astigmatic curvature produced by concave spherical lenses resulting in increased accommodative effort with overaction of convergence (esophoria).

Subjectively, I have simple hyperopic astigmatism of 0.75 D. in each eye, accepting + 0.75c. ax. about 75 degrees, O. D., and same cylinder axes, exactly 105 degrees, O. S.

My corneæ have been repeatedly and carefully measured by different observers, and I have the faculty of converging moderately or excessively with either eye alone, the other remaining motionless in the primary position. On converging, the reflected and tangent images of the mires are always seen to separate in the meridian of least curvature 0.25 D., and to overlap in the one of greatest curvature from 0.12 to 0.25 D. Measurements on the arcs of the instrument give like results. Besides this, the principal meridians of each eye are shifted. Each nearly horizontal meridian inclining nasally 15 degrees, and each nearly vertical one outward 10 to 15 degrees, as shown in Fig. 14.

Taking the left eye, when converging the right on a point 8 to 10 inches in the median line, the tangent images at meridian 15 degrees of the left cornea are seen to separate from 0.25 D. to 0.37 D., and to overlap about 0.12 D. near the meridian of 105 degrees. I say *near* these meridians because the principal meridian 15 degrees now becomes 30 degrees, and 105 degrees becomes 90 degrees; the more horizontal (15 degrees) inclining nasally 15 degrees, and 105 degrees inclining temporally 15 degrees.

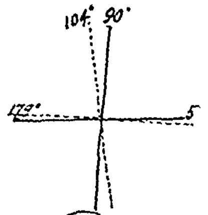

Fig. 15.

A fellow physician has in the left eye a corneal astigmatism 15 degrees ± 0.75 D. On convergence, in contrast to my own case, the horizontal meridian inclines outward 6 degrees and the vertical 9 degrees inward, the curvature increasing slightly in each. (Fig. 15, the dotted lines indicate the meridians during convergence.)

In order to determine whether or not by subjective tests there is dynamic astigmatism produced in my left eye by simultaneous convergence and accommodation, and whether this bears any direct relation to the corneal asymmetry similarly induced, during three years I have proceeded as follows: With my correction, +0.75c. ax. 105 degrees, before this eye, the right covered, I regard an astigmatic chart and tangent scale at 6 meters. The dial lines appear equal and clear; exophoria 2 degrees. Now, placing a minus 3.00 D. sphere before the left eye and cylinder, and by a strong effort of accommodation overcoming the induced hyperopia, esophoria of 18 to 20 degrees is induced (9 to 10 degrees of actual deviation, equivalent to convergence on a point of close to 8 inches). The chart lines 30, 45 and 60 degrees now alone appear distinct, and all the lines are equalized by +0.50 cyl. axis 135 degrees, indicating either a decreased relative curvature in the corneal meridian 45 degrees, or an increased one in meridian 135 degrees. The result of this experiment never varies, and it proves conclusively the production of dynamic astigmatism due either to accommodation or convergence, or both. Apparently, there is a direct relation between the corneal astigmatism produced in the left cornea by both objective and subjective experiments (Fig. 14).

---

[12] Norris and Oliver, vol. iv., pp. 430, 431.
[13] Ophth. Rev., vol. iv, p. 354.

The inclination of the principal meridians in my own eyes can not be explained by the outward physiologic torsion, which, according to Le Conte's laws, occurs in horizontal convergence from the primary position; for experiments show that this outward torsion of my eyes, converging to 8 inches, amounts to only 3 degrees, whereas, as seen in Fig. 14, the outward inclination of the nearly vertical meridians amounts to 10 and 15 degrees, while the nearly horizontal ones actually incline inward. There is, therefore, a distortion of the corneæ, and this, I believe, is due to pressure during convergence by the superior, inferior and internal recti. This pressure is quite as great in marked esophoria of accommodative origin.

In concluding this paper, I insist that dynamic astigmatism is of practical clinical importance, and the gist of my demonstration is a plea to consider in many cases the total refractive error in doubt until time, cycloplegic's rest, aided if necessary by the hypodermic use of hyoscin hydrobromate and bromids or other sedatives, with patient "fogging" at times, has eliminated all dynamic contractions. The condition is frequent, not rare, and failure to recognize it often accounts for the discrepancies in the refractive findings of competent ophthalmologists.

590 Sutter Street.

DISCUSSION.

Dr. William Campbell Posey, Philadelphia, declared that the paper offered a satisfactory explanation to him of his failure to relieve some three or four cases during the last two or three years. He had refracted each eye separately very carefully, under a mydriatic, and had established the fact to his satisfaction that the axis of astigmatism in each eye was, say, at 90 degrees. The lenses were then ordered with the cylinders at this axis. In a few days, however, the patients returned, saying that the glasses did not give comfort, and that they noticed that if the lenses were slightly tilted they gave better vision and comfort. The work was then gone over a second time, only to find that when tested monocularly the axis was at 90 in each eye; with both eyes open, however, and the lenses in position, it was found that the axis of the astigmatism in one of the eyes had shifted about 10 degrees. That this change was due to an unusual action of one of the extraocular muscles on the eye Dr. Posey thinks there can now be no doubt.

Dr. D. de Beck, Seattle, Wash., related that during college life he was perfectly well in every way, but suffered from asthenopic headaches and in the beginning of his medical studies he still suffered; when he began eye work he found that either eye could read 20/20 readily. His eyes were tested under atropin by his late teacher, Dr. Seeley, who found that he had a simple hypermetropic astigmatism of 1.50 D., with an inclined axis, 105 in the right and 75 in the left. With these he saw perfectly well and has worn that correction for twenty-five years. He also had a slight but well marked cyclophoria. On taking off these glasses at that time he would find that he had a vision of 20/70, but that in a little while he could work down the line until he could read 20/20. Putting on the glasses would for a few moments blur the vision and then he would again have 20/20 vision. In other words, he could adjust for the defect, but as years went by the adjustment became less and less perfect. This personal obesrvation Dr. de Beck thought was in line with Dr. Eaton's experience.

Dr. Mark D. Stevenson, Akron, Ohio, said that when lenses having strong cylinders are prescribed, he rotates them in their frames until they are in the correct position before the eyes, so that the axis of each cylinder may correspond to one of the chief meridians of each eye. In doing so he has observed that the directions of the principal meridians sometimes change when binocular single vision replaces the vision of one eye. He has also observed this change during the act of accommodation.

THE INCIDENCE OF HEART DISEASE IN SAN FRANCISCO.*

WILLIAM FITCH CHENEY, M.D.
Professor of Principles and Practice of Medicine, Cooper Medical College, and Physician to Lane Hospital.
SAN FRANCISCO.

My object in writing this paper is to throw some light on the frequency of organic heart disease in San Francisco; on the relative frequency of the various forms; and on the factors that make the frequency what it is. In order to accomplish this purpose I have drawn on two sources of information. The first of these is the records of the General Medical Clinic in the dispensary of Cooper Medical College; and the second is the autopsies performed by my colleague, Dr. William Ophüls, professor of pathology in Cooper Medical College. In the medical clinic I have had opportunity for personal investigation of the cases concerned in the preparation of this paper, and know the facts to be as stated. As regards the autopsies, they were all made by Dr. Ophüls himself, who has kindly placed his personal records at my disposal.

Some explanation must be given at the outset as to what has been included under the term "heart disease." It is so often difficult to decide that the heart is really unsound, and that the heart symptoms of which complaint is made are not, in fact, due to disease of some other organ. Every clinical investigator must have certain rules for his guidance, and it is only fair to state first of all what rules have been followed in determining the presence of heart disease in the cases herewith reported.

First.—Although it may seem superfluous to state that no case has been diagnosed on symptoms alone, yet this statement is not superfluous, because such diagnoses are sometimes made.

Second.—No case in the group reported has been diagnosed on physical signs alone, especially not by the mere presence of murmurs. Nothing is more familiar to the teacher of medicine than the certainty with which a medical student rushes from the discovery of a murmur to the conclusion that valvular disease exists; while with increasing experience the murmur itself becomes less and less important as an indication of organic disease. I would not have it suspected, therefore, that diagnoses have been made in this way among the cases collected. On the contrary, so great has been the anxiety for conservatism in diagnosis, that no cases have been set down in the records as heart disease unless besides the murmur there was definite evidence present of alteration in the area of cardiac dullness, with symptoms and signs of broken compensation, either at the time of the first examination, or previous or subsequent to it. In other words, heart disease has not been considered to exist, unless it caused some, at least, of the well-known symptoms and gave rise also to the well-known physical signs.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Third.—Cases of cardiac neurosis have been entirely excluded. The patient that comes complaining of the heart is one of the most common visitors at any dispensary clinic; but rarely are such patients found to have organic disease of the heart. Naturally among the class who apply at an out-door clinic, there are many of the victims of various forms of dissipation and excess. Poverty, ignorance and vice do not always go hand in hand, but they are extremely frequent associates in the people with whom we have to deal. The various forms of cardiac neurosis—palpitation, tachycardia, heart pain, consciousness of heart action, have been observed even more frequently amongst our patients than real heart disease. But these false cases have been carefully distinguished from the true and all have been omitted in making up the list presented in this paper.

Fourth.—Still another point to be made clear is, that cases of hypertrophy or of dilatation of the heart, secondary to some other disease, have not been included in this list. For instance, in all the cases of chronic nephritis with secondary heart changes, no record has been made in this group of heart cases. Similarly with cirrhosis of the liver, pulmonary tuberculosis, the primary anemias and diabetes, no cases have been recorded as having heart disease, no matter what secondary changes were manifest in the heart. In other words, our effort has been to limit the inquiry to cases in which the heart was plainly the organ primarily diseased. The greatest difficulty has been encountered in the effort to determine the relation of arteriosclerosis to myocardial changes. Here it has been found practically impossible to decide whether one or the other process first took place, or whether they both developed simultaneously. In no case, however, has myocarditis been diagnosed without the presence of definite symptoms and physical signs referable to the heart, no matter what grade of arteriosclerosis was demonstrable in the peripheral vessels.

I. FREQUENCY OF HEART DISEASE IN SAN FRANCISCO.

After these preliminary explanations I pass to the consideration of the first question, viz.: How often does heart disease occur in San Francisco? I have looked over the records of 3,648 cases seen in the medical clinic of Cooper Medical College, during the five years from Jan. 1, 1900, to Jan. 1, 1905. Among these there occurred 135 of organic disease of the heart. Ninety-seven of these cases came to the clinic with the symptoms and signs of broken compensation. In the other thirty-eight compensation was fair at the time of examination, but the physical signs were nevertheless definite and there was a history of broken compensation on some previous occasion. Several of the cases came to the clinic repeatedly with attacks of broken compensation occurring again and again during the five years. The percentage of heart cases was therefore 3.7, or, in other words, out of every thousand who presented themselves for all sorts of medical diseases, thirty-seven were found to have unsound hearts.

The records of autopsies by Dr. Ophüls number 640. Among these autopsies sixty-one showed organic disease of the heart. This makes a percentage of 9.5; which means that out of one thousand cases of death from all causes, ninety-five bodies showed organic disease of the heart. The marked discrepancy between the clinical figure and the pathologic figure may be explained in several different ways.

First.—It is common for people with a slight degree of organic change in the heart to have no symptom of ill health referable to these changes; and to die from some other acute illness, when systematic investigation at autopsy reveals lesions not previously suspected to exist.

Second.—Slight changes in the structure of the heart valves and heart muscle may give rise to such dubious physical signs that the clinician may not recognize their presence, even though he has sought for them.

Third.—The total number of cases is very different in the two sets of records; and if the total number were equal in each, the proportion of heart cases might be more alike.

Fourth.—It must be remembered that the cases taken from the clinic records were all ambulatory; while Dr. Ophüls' autopsies were made almost entirely upon cases that died in the City and County Hospital, or in Lane Hospital. People who go to a dispensary clinic must of necessity be well enough to get about; but people who go to bed in a hospital, do so because they are too ill to be any longer about. Once in a hospital they are very likely to reach the pathologist, and once in the hands of a competent pathologist things are sure to be found out about them that were never known before. It is impossible, therefore, to draw any final conclusion as to the exact incidence of heart disease in this city, and as to where it lies between 37 per thousand as a minimum and 95 per thousand as a maximum. So far as I can find out, no previous attempt to establish this has been made, and this pioneer effort must of necessity give only an approximate estimate.

II. RELATIVE FREQUENCY OF THE VARIOUS FORMS.

In considering this point, a number of cases were naturally found where there appeared to be a lesion at more than one valve; but in these cases the diagnosis was always made of the lesion that seemed to predominate and to control not only the physical signs but also the clinical history. As was to be expected, the lesion most often met with was mitral regurgitation, of which there were sixty-five cases. Next in frequency came myocarditis, of which there were forty cases. While it is recognized that it is never possible to say with absolute certainty whether the myocardial change is fibroid or fatty in character, still in an overwhelming majority of the myocarditis cases there were associated changes in the vessels which spoke for fibroid change; and in only five did it seem likely that the condition present was a fatty degeneration of heart muscle. It has seemed to us that the proportion of myocardial disease to valvular disease is rather a large one, and this conviction based on clinical observation seems to be borne out by the pathologic findings in Dr. Ophüls' autopsy reports, as will presently appear. Third in order of frequency came aortic regurgitation, of which twenty-one cases were observed. All of them were typical and in two of them that died during the time of their attendance on the clinic, autopsy confirmed the diagnosis. Finally there were observed nine cases of pure mitral stenosis. I am convinced that this number does not convey a proper idea of the frequency of this lesion; but as no patients under 12 years of age are admitted to this clinic, and as mitral stenosis is essentially a lesion of childhood, naturally the number herewith reported falls far behind the other forms. As it is, seven of the nine cases observed were in individuals under 20. No case was seen where a diagnosis of aortic stenosis could conscientiously be made.

Turning now to Dr. Ophüls' autopsy reports, out of the sixty-one cases of heart disease discovered, forty-three were cases of endocarditis and eighteen of myocarditis. As regards the orifices affected, the aortic alone was found involved eleven times; in one case no severe lesion, in three cases largely stenosis, and in seven cases insufficiency. The mitral alone was found involved ten times; in seven cases no severe lesion, in one case largely stenosis, in one case largely insufficiency, and in one case both. Both aortic and mitral valves were found involved simultaneously seventeen times. In the eighteen cases of myocarditis, fourteen showed partial obstruction of the coronary arteries by arteriosclerosis.

The observations made as regards the relative frequency of the various forms of organic heart disease are, therefore, not essentially different from those of observers elsewhere; except that there seems to be an unusual proportion amongst our cases of disease of the myocardium. This is directly attributable to the great frequency of arterial disease amongst the class of patients we meet in our clinic, a fact which accounts also, I may say in passing, for the remarkable frequency with which we observe aneurism of the aortic arch in San Francisco—a fact to which I venture to call attention at this time, without adducing statistics to corroborate the statement.

III. FACTORS INFLUENCING THE FREQUENCY.

(*A*) *Rheumatism.*—As one would expect, articular rheumatism has played a prominent part in the history of our cases who came with heart disease. Forty-nine in all had either had rheumatism at some time in their previous history, or were suffering from a subacute attack at the time of their visit. In a number of these there was the usual history of frequently recurring attacks; in others simply a history of one severe illness with a few or many joints involved. It is interesting to note the relation of rheumatism to the form of lesion present. Out of nine cases diagnosed as mitral stenosis, six had a positive history of rheumatism, usually of recurring attacks. Of the sixty-five cases of mitral regurgitation, thirty-three had an antecedent history of rheumatism. On the other hand, out of twenty-one cases of aortic regurgitation, only five had an antecedent history of rheumatism and out of the forty cases of myocarditis, only seven had ever suffered previously from rheumatism. Thus it would appear that while in San Francisco, as elsewhere, the acute infectious disease called rheumatism frequently leads to organic disease of the heart, it is the mitral valve that is most often left incapaciated, while the aortic much more frequently escapes and the myocardium suffers least frequently of all.

(*B*) *Arteriosclerosis.*—This is naturally the second great factor. It has been found present in practically all of the cases diagnosed as myocarditis, and in a large proportion of the cases of aortic regurgitation. It is recognized as a matter of course that arteriosclerosis may be manifestly present in peripheral vessels and yet, perhaps, play no part in the condition of the heart; and, on the other hand, that before changes can be discovered in peripheral vessels, advanced change may already have occurred in the coronary arteries and in the aortic arch. But two points are absolutely certain:

First.—The extreme frequency with which we observe arteriosclerosis in the clinic, as shown by thickened and hardened walls in the palpable peripheral vessels.

Second.—The fact that out of the eighteen cases of myocarditis which were found among Dr. Orphüls' autopsies, fourteen showed a greater or less degree of obstruction of the coronaries by arteriosclerosis.

Whatever the reason for it may be, degeneration of vessels is, without doubt, one of the most conspicuous pathologic conditions with which we meet in the medical clinic from which these records are taken.

(*C*) *Nationality.*—It is a significant fact that, out of the 135 cases, only forty-eight were of native stock—that is, born in the United States. What bearing this may have on the incidence of heart disease is not readily explained, but the fact remains that nearly two-thirds of our cases were of foreign birth. Nothing shows better than these statistics of a medical clinic how cosmopolitan is the population of San Francisco. Among the cases collected there were patients from Austria, Ireland, Germany, Sweden, Denmark, Italy, England, Canada, Poland, France, Switzerland, Finland, Roumania, Russia, West Indies, Belgium, Portugal, Norway, Hungary; while in the clinic, though not represented among the heart cases, we have frequent visits from Chinese and Japanese. Returning to the relation which foreign birth may bear to heart disease, the only explanation I can offer, based on my observation of these people as they come to us, is that the foreigners are afflicted not only by poverty, as all visitors at a free clinic must necessarily be, but are almost invariably filthy in their habits, addicted to the use of alcohol and tobacco, and ignorant of all proper conception of how they should live, of how they should eat, drink, work and house themselves in order to maintain health.

(*D*) *Occupation.*—It can be safely asserted that among our cases, no one occupation has predisposed more than another to heart disease; for almost every conceivable form of labor is represented among the 135 collected here. But it must be borne in mind, on the other hand, that only the laboring class are represented in this group, and that no information whatever is given by a public clinic as to the frequency of heart disease among the prosperous, whose occupation is entirely different from that of the class from whom these cases come. It is not likely that the occupation itself has so much to do with the incidence of heart disease as has the association of any hard work with bad hygienic habits, poor food, overindulgence in alcohol and other forms of dissipation. While I have no definite statistics to offer as to the frequency of heart disease in private practice, my impression is that cases are not so frequently met with among the well-to-do as among the poor; and not so frequently among those who earn their living by their brains as among those who have to earn their daily bread by the work of their hands. Nevertheless, the rich, the idle, and the brain workers have diseases of their own, even if they apparently escape their share of heart disease.

(*E*) *Sex.*—Only thirty-five of the cases were women, while one hundred were men. While the fact that the number of males in the group so largely exceeds the females may be partly explained by the fact that the number of men presenting themselves for treatment at a dispensary clinic is always greater than the number of women, still there is no such disproportion in the attendance as there is in the number of these cases of heart disease; and the inference seems justifiable that in San Francisco, at least, heart disease is more common among men than among women.

(*F*) *Age.*—As is well known, there is no time of life exempt from heart disease, and our cases were found distributed among individuals of every age from 12 as a minimum to 81 as a maximum. During the various decades they occurred as follows: 12 to 20, nine; 20 to 30, sixteen; 30 to 40, seventeen; 40 to 50, thirty-two; 50 to 60, twenty-nine; 60 to 70, twenty-six; 70 to 80, six. Of the nine cases under 20, seven were mitral stenosis and two mitral regurgitation; of the sixteen between 20 and 30, ten were mitral regurgitation, two were aortic regurgitation, two were mitral stenosis and two only were diagnosed as myocarditis. Of the seventeen cases between 30 and 40, ten were mitral regurgitation, five were aortic regurgitation and only two were myocarditis. Thus it will be seen that all of the cases of mitral stenosis occurred under the age of 30 and the great majority under 20; while, on the other hand, out of the forty cases in all of myocarditis, only four were observed in patients under 40. The mitral regurgitations were found quite evenly distributed throughout all the decades, almost the same number for each ten years up to 70; which would seem to indicate not only that mitral regurgitation has no predilection for any particular time of life, but also that its prognosis is better than that of the other valvular lesions. Of the aortic regurgitations only one-third occurred under the age of 40, and two-thirds between the ages of 40 and 60; which would seem to indicate the part played in the production of this lesion by arteriosclerosis. This, indeed, is the most significant fact that stands out above all others in these records—the predominance of arterial disease; and advanced years in themselves lead to heart disease only as they first lead to changes in the coronary arteries, or in the aortic arch and the valves that guard the orifice of this great vessel.

CONCLUSIONS.

1. Heart disease is a common ailment in San Francisco, as it is in all large cities.

2. Among valvular troubles, the form most commonly met with is mitral regurgitation; second comes aortic regurgitation, and, third, mitral stenosis, while aortic stenosis is undoubtedly a rare affection.

3. Myocardial disease is frequently found. The factors in its incidence are those commonly supposed to cause arteriosclerosis; and the latter condition is even more often seen than myocarditis itself.

DISCUSSION.

Dr. W. Ophüls, San Francisco, said that the number of cases examined at postmortem was rather small, and a comparatively small number for statistical purposes. He was struck with the large number of septic endocarditis cases. Nearly all of these cases were diagnosticated clinically as cases of chronic rheumatism with heart lesions and Dr. Ophüls thought that the cases of rheumatism, so-called, that lead to severe lesions of the heart valves were, in the large majority, more properly speaking cases of sepsis. How frequently these heart lesions follow in instances of rheumatism, if we want to acknowledge the existence of such a condition not due to an infection with ordinary septic bacteria, is another matter. It can not occur very frequently. So that it is presumable in the course of a disease with the clinical picture of polyarticular rheumatism, but with severe lesions of the heart valves, that the condition really is a septic one.

Dr. James J. Walsh, New York, thought, with regard to the origin of rheumatic endocarditis, that there is a definite change of opinion among medical men about to come that is worth while noting. At the present time it is generally accepted that simple acute articular rheumatism is very frequently followed by valvular heart disease; on the other hand, it is generally acknowledged that simple, articular rheumatism *does not leave any marked evidence of disease in* the joints. One of the pathognomonic signs of acute articular rheumatism is that it leaves no mark after it. Whenever a chronic arthritic condition remains there is more than a suspicion that the original disease was not simple acute rheumatism, but either arthritis deformans or acute arthritis, due to some other infection beside that which produces true rheumatism. Affections of the heart valves are extremely common in septic conditions of all kinds. There is scarcely any form of microbe that gets into the circulation but will not produce an affection of these delicate structures. The heart valves are, after all, joints in the tissues, that is, they represent portions of the tissues covered by serous membranes in order that they may move over one another without friction and without adhesion. Since ordinary acute rheumatism when uncomplicated does not leave any mark on the other joints in the body, it seems probable that it also does not leave any mark on the heart; at least, not nearly in the large proportion usually stated. When there is a so-called rheumatic endocarditis it is probable that there has been some secondary affection complicating the simple rheumatic arthritis. This point of view can not but be helpful for diagnosis and prognosis.

Dr. Charles Rollins Grandy, Norfolk, Va., reported that his experience with heart disease among the negroes has been rather different. Heart disease among the negroes is very common, while acute rheumatism is seldom seen. The negroes have various other diseases which they call chronic rheumatism, but which are probably nervous affections, etc. Many cases of aortic valve murmurs or even double valve murmurs occur. There may be an aortic direct murmur, although at autopsy there will not be found any closing of the valves. Men who do heavy work have dilated hearts, hypertrophied hearts, with a leak at the mitral or other valves; these are some of the cases that come to Dr. Grandy for treatment in Norfolk. In probably the majority of them there was a strain of the valve. They were young men and Dr. Grandy was able to note the blood pressure and the arteriosclerosis.

ACUTE DIFFUSE SUPPURATIVE PERITONITIS.*

SIMON J. YOUNG, M.D.
VALPARAISO, INDIANA.

Many men of many minds have written about peritonitis. The theme is old but not exhausted—not while surgeons are reporting 100 per cent. of mortality. I shall confine myself to a discussion of the acute diffuse suppurative form of the disease, and will consider especially the treatment. For etiology and classification I will refer to the publications of Senn[1] and Bayard Holmes,[2] whose monographs are exhaustive and scholarly.

In the study of this subject my purpose has been to secure for comparison the experiences, methods and opinions of a considerable number of surgeons. This I have undertaken by correspondence and by some references to literature. Fifty letters were addressed to surgeons in various sections of the country, information being sought on lines suggested by the following questions:

---

* Read before the Indiana State Medical Association, June 8, 1905.

1. Senn.: Journal A. M. A., Sept. 4, 1897.
2. Holmes: Illinois Med. Jour., 1904, vi, 499-515.

1. Do you make it a rule to operate on acute diffuse suppurative peritonitis?
2. If not, what are the contraindications?
3. On how many cases have you operated, and with what mortality?
4. What is your method of operation and treatment?
5. Do you ever refuse to operate? If so, when and why?

Free discussion was invited. Twenty-five answered—some in detail. A dozen sent courteous regrets. From the remainder no answers were received. Many of the letters received were scholarly and instructive. I wish I might publish them in full, but that is manifestly inexpedient. I, therefore, give you briefs and excerpts as follows:

Van Buren Knott, Sioux City, was among those who gave detailed information as to his methods of treatment. He always operates unless patient is moribund. He has kept records only since 1902. Since that date he has operated on 19 cases, with 17 recoveries and 2 deaths. He employs the median incision, and at once repairs any leak or diseased part that may exist. Through a two-inch incision above the symphysis he places a tube one and one-half inches in diameter, carrying a gauze wick to the bottom of the pelvis. In females a similar tube without the gauze wick is placed in the cul-de-sac. Gallons of hot salt solution are used to flush the abdomen, enough of which is left in to fill the cavity entirely. With an additional drainage tube in the pelvis similar to the first, but without the wick, the patient is raised to the Fowler attitude while yet on the table, transferred to the bed and kept in this position. Through this plain tube in the pelvis he pumps out, every two hours, such excess of fluids as are not carried off by the wick. This is done for 24 hours. He thinks by leaving in the abdominal cavity a large amount of the saline solution a strong current is established toward the lower pelvis.

D. N. Eisendrath, Chicago, operates on all cases where diagnosis has been made during the first 24 to 72 hours. As contraindications, he mentions extreme sepsis as shown by a pulse of 180 to 200, excessive distention of the abdomen which denotes a complete septic paralysis of the gut, as well as constant vomiting. He thinks these latter cases, however, are those in which a diagnosis has not been made until the fourth, fifth or sixth day after the onset of perforation. Prior to his adoption of the Fowler position, he reports 7 cases with a mortality of 100 *per cent.* Since using the Fowler position he has had 3 cases, all of which recovered. He washes the abdominal cavity with three or four gallons of hot salt solution and inserts a Mikulicz (or umbrella) drain of plain gauze. Where the drain goes through the skin it is surrounded with long strips of loosely folded gauze, which is frequently changed within the first few days after the operation.

Joseph R. and Thomas B. Eastman, Indianapolis, make it a rule to operate on all cases unless moribund. They report 7 cases with 1 death. Their method is celiotomy, lavage, very gentle manipulation of the intestines in search for abscess or perforation, and tube drainage from bottom of pelvis, with patient in Fowler's position.

George Tully Vaughan, Washington, D. C., reports 16 cases, with 4 recoveries and 12 deaths. He uses irrigation and drainage and refuses to operate only when patient is moribund.

John A. Wyeth, New York, does not operate on all cases. In cases of seemingly diffuse mild peritonitis, progressing slowly from the first indications of the disease, he adopts the Fowler position, gives calomel and flushes the colon from below with salines. He reports two cases within two years of general diffuse peritonitis in children which had developed in connection with colitis due to intestinal indigestion, and both were relieved, without operation, by this method. Rapidly developing general peritonitis, from symptoms of gangrene of the appendix or perforation, he says, require operation, and the seat of infection should be sought out and removed. He flushes with sterile water 100 to 105 degrees, with a long tube, beginning above the liver, spleen and stomach, and underneath these organs, and around on either side, carefully, under high pressure, using volumes of water until the fluid comes out clear. In women he opens the cul-de-sac and drains, and in men through an opening above the pubes he puts in a pelvic pack.

Roswell Park is among those who take a pessimistic view of operative treatment. He says: "I have had such a small measure of success in attacking diffuse suppurative peritonitis that I avoid operation on it if I possibly can. I feel that the contraindication is the fact of its being suppurative and diffuse."

J. F. Binnie, Kansas City, says that operation is the only logical method of treatment, but that he has seen more cases recover unexpectedly without operation than with. He is convinced that almost all cases where the abdomen is much distended and diffuse suppuration is present will die, no matter what the treatment.

James E. Moore, Minneapolis, and John P. Roberts, Philadelphia, also incline to this view.

Parker Syms, Philadelphia, makes it a rule to operate on diffuse cases. He says: "I believe there should be a careful distinction made between diffuse and general acute suppurative peritonitis. I believe that general acute suppurative peritonitis is fatal in 100 per cent. of cases, no matter what plan of treatment is employed. I believe diffuse peritonitis should give satisfactory results if properly operated on. Of course, there will be a pretty high mortality rate. My method is removal of the original focus, sponging out of the sero-pus and careful drainage with gauze and rubber tissue. I use peroxid of hydrogen locally. I do not believe in flushing. In the routine after operation I employ the physiologic rest to the stomach and alimentary canal as prescribed by Ochsner. I often prescribe the upright position suggested by Fowler."

L. L. McArthur, Chicago, operates except in the moribund state. He reports 100 cases, out of which he saved 23. He uses irrigation, pelvic drainage and the Fowler position.

This plan of treatment is endorsed by Robert G. LeConte, B. F. Curtis and De Forest Willard, Philadelphia; Chas. A. Powers, Denver, and H. L. Burrell, Boston.

B. F. Curtis, Philadelphia, also recommends the ice coil and opium.

H. L. Burrell, Boston, reports "at least 100 cases," and recalls "a few instances in which recovery has occurred." Occasionally when in doubt as to how diffuse the peritonitis is, he uses Ochsner's treatment for a few days.

Nicholas Senn, Chicago, has no fixed rule for operating. He selects his cases. He claims as contraindications, subnormal temperature, pulse 150 or more and great abdominal distension. He could not state the number of cases on which he had operated. His method consists of free drainage, flushing, and, if necessary, multiple incisions.

W. J. Mayo, Rochester, Minn., reports about 30 cases, with at least 50 per cent. of recoveries. He advocates quick abdominal incision and pelvic drainage with the patient kept in a *sitting* position for four or five days. Contraindications are general sepsis, leaky skin, quick pulse and cyanosis.

R. C. Coffey, Portland, Ore., makes it a rule to operate on all cases, except in extreme shock, or in which the condition has existed for several days and the patient is improving or is growing no worse. His treatment consists chiefly in carefully applied capillary drainage in sufficient quantities absolutely to dry the abdominal cavity within an hour or less time. For this purpose he has used more than 100 drains in wicks the size of a finger in extreme cases. In addition to drainage, he has great faith in anti-streptococcic serum or streptolytic serum. He commends Ochsner's method of starvation and stomach washing in these cases.

C. H. Mayo, Rochester, Minn., operates if due to rupture of viscera; also in the earlier stage of ruptured abscess if patient is reacting. He does not operate if patient is in the second period of subnormal temperature following the shock of rupture. In case of a ruptured viscus, the source is found and cared for, foreign material removed by irrigation, large females may be partly explained by the fact that the number of men presenting themselves for treatment at a dispensary clinic is always greater than the number of women, still there is no such disproportion in the attendance as there is in the number of these cases of heart disease; and the inference seems justifiable that in San Francisco, at least, heart disease is more common among men than among women.

(*F*) *Age.*—As is well known, there is no time of life exempt from heart disease, and our cases were found distributed among individuals of every age from 12 as a minimum to 81 as a maximum. During the various decades they occurred as follows: 12 to 20, nine; 20 to 30, sixteen; 30 to 40, seventeen; 40 to 50, thirty-two; 50 to 60, twenty-nine; 60 to 70, twenty-six; 70 to 80, six. Of the nine cases under 20, seven were mitral stenosis and two mitral regurgitation; of the sixteen between 20 and 30, ten were mitral regurgitation, two were aortic regurgitation, two were mitral stenosis and two only were diagnosed as myocarditis. Of the seventeen cases between 30 and 40, ten were mitral regurgitation, five were aortic regurgitation and only two were myocarditis. Thus it will be seen that all of the cases of mitral stenosis occurred under the age of 30 and the great majority under 20; while, on the other hand, out of the forty cases in all of myocarditis, only four were observed in patients under 40. The mitral regurgitations were found quite evenly distributed throughout all the decades, almost the same number for each ten years up to 70; which would seem to indicate not only that mitral regurgitation has no predilection for any particular time of life, but also that its prognosis is better than that of the other valvular lesions. Of the aortic regurgitations only one-third occurred under the age of 40, and two-thirds between the ages of 40 and 60; which would seem to indicate the part played in the production of this lesion by arteriosclerosis. This, indeed, is the most significant fact that stands out above all others in these records—the predominance of arterial disease; and advanced years in themselves lead to heart disease only as they first lead to changes in the coronary arteries, or in the aortic arch and the valves that guard the orifice of this great vessel.

CONCLUSIONS.

1. Heart disease is a common ailment in San Francisco, as it is in all large cities.

2. Among valvular troubles, the form most commonly met with is mitral regurgitation; second comes aortic regurgitation, and, third, mitral stenosis, while aortic stenosis is undoubtedly a rare affection.

3. Myocardial disease is frequently found. The factors in its incidence are those commonly supposed to cause arteriosclerosis; and the latter condition is even more often seen than myocarditis itself.

DISCUSSION.

Dr. W. Ophüls, San Francisco, said that the number of cases examined at postmortem was rather small, and a comparatively small number for statistical purposes. He was struck with the large number of septic endocarditis cases. Nearly all of these cases were diagnosticated clinically as cases of chronic rheumatism with heart lesions and Dr. Ophüls thought that the cases of rheumatism, so-called, that lead to severe lesions of the heart valves were, in the large majority, more properly speaking cases of sepsis. How frequently these heart lesions follow in instances of rheumatism, if we want to acknowledge the existence of such a condition not due to an infection with ordinary septic bacteria, is another matter. It can not occur very frequently. So that it is presumable in the course of a disease with the clinical picture of polyarticular rheumatism, but with severe lesions of the heart valves, that the condition really is a septic one.

Dr. James J. Walsh, New York, thought, with regard to the origin of rheumatic endocarditis, that there is a definite change of opinion among medical men about to come that is worth while noting. At the present time it is generally accepted that simple, acute articular rheumatism is very frequently followed by valvular heart disease; on the other hand, it is generally acknowledged that simple, articular rheumatism does not leave any marked evidence of disease in the joints. One of the pathognomonic signs of acute articular rheumatism is that it leaves no mark after it. When there is a so-called rheumatic endocarditis it is probable that there has been some secondary affection complicating the simple rheumatic arthritis. This point of view can not but be helpful for diagnosis and prognosis.

Dr. Charles Rollins Grandy, Norfolk, Va., reported that his experience with heart disease among the negroes has been rather different. Heart disease among the negroes is very common, while acute rheumatism is seldom seen. The negroes have various other diseases which they call chronic rheumatism, but which are probably nervous affections, etc. Many cases of aortic valve murmurs or even double valve murmurs occur. There may be an aortic direct murmur, although at autopsy there will not be found any closing of the valves. Men who do heavy work have dilated hearts, hypertrophied hearts, with a leak at the mitral or other valves; these are some of the cases that come to Dr. Grandy for treatment in Norfolk. In probably the majority of them there was a strain of the valve. They were young men and Dr. Grandy was able to note the blood pressure and the arteriosclerosis.

ACUTE DIFFUSE SUPPURATIVE PERITONITIS.*

SIMON J. YOUNG, M.D.
VALPARAISO, INDIANA.

Many men of many minds have written about peritonitis. The theme is old but not exhausted—not while surgeons are reporting 100 per cent. of mortality. I shall confine myself to a discussion of the acute diffuse suppurative form of the disease, and will consider especially the treatment. For etiology and classification I will refer to the publications of Senn[1] and Bayard Holmes,[2] whose monographs are exhaustive and scholarly.

In the study of this subject my purpose has been to secure for comparison the experiences, methods and opinions of a considerable number of surgeons. This I have undertaken by correspondence and by some references to literature. Fifty letters were addressed to surgeons in various sections of the country, information being sought on lines suggested by the following questions:

---

* Read before the Indiana State Medical Association, June 8, 1905.

[1] Senn.: Journal A. M. A., Sept. 4, 1897.

[2] Holmes: Illinois Med. Jour., 1904, vi, 499-515.

1. Do you make it a rule to operate on acute diffuse suppurative peritonitis?
2. If not, what are the contraindications?
3. On how many cases have you operated, and with what mortality?
4. What is your method of operation and treatment?
5. Do you ever refuse to operate? If so, when and why?

Free discussion was invited. Twenty-five answered—some in detail. A dozen sent courteous regrets. From the remainder no answers were received. Many of the letters received were scholarly and instructive. I wish I might publish them in full, but that is manifestly inexpedient. I, therefore, give you briefs and excerpts as follows:

Van Buren Knott, Sioux City, was among those who gave detailed information as to his methods of treatment. He always operates unless patient is moribund. He has kept records only since 1902. Since that date he has operated on 19 cases, with 17 recoveries and 2 deaths. He employs the median incision, and at once repairs any leak or diseased part that may exist. Through a two-inch incision above the symphysis he places a tube one and one-half inches in diameter, carrying a gauze wick to the bottom of the pelvis. In females a similar tube without the gauze wick is placed in the cul-de-sac. Gallons of hot salt solution are used to flush the abdomen, enough of which is left in to fill the cavity entirely. With an additional drainage tube in the pelvis similar to the first, but without the wick, the patient is raised to the Fowler attitude while yet on the table, transferred to the bed and kept in this position. Through this plain tube in the pelvis he pumps out, every two hours, such excess of fluids as are not carried off by the wick. This is done for 24 hours. He thinks by leaving in the abdominal cavity a large amount of the saline solution a strong current is established toward the lower pelvis.

D. N. Eisendrath, Chicago, operates on all cases where diagnosis has been made during the first 24 to 72 hours. As contraindications, he mentions extreme sepsis as shown by a pulse of 180 to 200, excessive distention of the abdomen which denotes a complete septic paralysis of the gut, as well as constant vomiting. He thinks these latter cases, however, are those in which a diagnosis has not been made until the fourth, fifth or sixth day after the onset of perforation. Prior to his adoption of the Fowler position, he reports 7 cases with a mortality of 100 per cent. Since using the Fowler position he has had 3 cases, all of which recovered. He washes the abdominal cavity with three or four gallons of hot salt solution and inserts a Mikulicz (or umbrella) drain of plain gauze. Where the drain goes through the skin it is surrounded with long strips of loosely folded gauze, which is frequently changed within the first few days after the operation.

Joseph R. and Thomas B. Eastman, Indianapolis, make it a rule to operate on all cases unless moribund. They report 7 cases with 1 death. Their method is celiotomy, lavage, very gentle manipulation of the intestines in search for abscess or perforation, and tube drainage from bottom of pelvis, with patient in Fowler's position.

George Tully Vaughan, Washington, D. C., reports 16 cases, with 4 recoveries and 12 deaths. He uses irrigation and drainage and refuses to operate only when patient is moribund.

John A. Wyeth, New York, does not operate on all cases. In cases of seemingly diffuse mild peritonitis, progressing slowly from the first indications of the disease, he adopts the Fowler position, gives calomel and flushes the colon from below with salines. He reports two cases within two years of general diffuse peritonitis in children which had developed in connection with colitis due to intestinal indigestion, and both were relieved, without operation, by this method. Rapidly developing general peritonitis, from symptoms of gangrene of the appendix or perforation, he says, require operation, and the seat of infection should be sought out and removed. He flushes with sterile water, 100 to 105 degrees, with a long tube, beginning above the liver, spleen and stomach, and underneath these organs, and around on either side, carefully, under high pressure, using volumes of water until the fluid comes out clear. In women he opens the cul-de-sac and drains, and in men through an opening above the pubes he puts in a pelvic pack.

Roswell Park is among those who take a pessimistic view of operative treatment. He says: "I have had such a small measure of success in attacking diffuse suppurative peritonitis that I avoid operation on it if I possibly can. I feel that the contraindication is the fact of its being suppurative and diffuse."

J. F. Binnie, Kansas City, says that operation is the only logical method of treatment, but that he has seen more cases recover unexpectedly without operation than with. He is convinced that almost all cases where the abdomen is much distended and diffuse suppuration is present will die, no matter what the treatment.

James E. Moore, Minneapolis, and John P. Roberts, Philadelphia, also incline to this view.

Parker Syms, Philadelphia, makes it a rule to operate on diffuse cases. He says: "I believe there should be a careful distinction made between diffuse and general acute suppurative peritonitis. I believe that general acute suppurative peritonitis is fatal in 100 per cent. of cases, no matter what plan of treatment is employed. I believe diffuse peritonitis should give satisfactory results if properly operated on. Of course, there will be a pretty high mortality rate. My method is removal of the original focus, sponging out of the sero-pus and careful drainage with gauze and rubber tissue. I use peroxid of hydrogen locally. I do not believe in flushing. In the routine after operation I employ the physiologic rest to the stomach and alimentary canal as prescribed by Ochsner. I often prescribe the upright position suggested by Fowler."

L. L. McArthur, Chicago, operates except in the moribund state. He reports 100 cases, out of which he saved 23. He uses irrigation, pelvic drainage and the Fowler position.

This plan of treatment is endorsed by Robert G. LeConte, B. F. Curtis and De Forest Willard, Philadelphia; Chas. A. Powers, Denver, and H. L. Burrell, Boston.

B. F. Curtis, Philadelphia, also recommends the ice coil and opium.

H. L. Burrell, Boston, reports "at least 100 cases," and recalls "a few instances in which recovery has occurred." Occasionally when in doubt as to how diffuse the peritonitis is, he uses Ochsner's treatment for a few days.

Nicholas Senn, Chicago, has no fixed rule for operating. He selects his cases. He claims as contraindications, subnormal temperature, pulse 150 or more and great abdominal distension. He could not state the number of cases on which he had operated. His method consists of free drainage, flushing, and, if necessary, multiple incisions.

W. J. Mayo, Rochester, Minn., reports about 30 cases, with at least 50 per cent. of recoveries. He advocates quick abdominal incision and pelvic drainage with the patient kept in a sitting position for four or five days. Contraindications are general sepsis, leaky skin, quick pulse and cyanosis.

R. C. Coffey, Portland, Ore., makes it a rule to operate on all cases, except in extreme shock, or in which the condition has existed for several days and the patient is improving or is growing no worse. His treatment consists chiefly in carefully applied capillary drainage in sufficient quantities absolutely to dry the abdominal cavity within an hour or less time. For this purpose he has used more than 100 drains in wicks the size of a finger in extreme cases. In addition to drainage, he has great faith in anti-streptococcic serum or streptolytic serum. He commends Ochsner's method of starvation and stomach washing in these cases.

C. H. Mayo, Rochester, Minn., operates if due to rupture of viscera; also in the earlier stage of ruptured abscess if patient is reacting. He does not operate if patient is in the second period of subnormal temperature following the shock of rupture. In case of a ruptured viscus, the source is found and cared for, foreign material removed by irrigation, large glass drain in the pelvis, patient in sitting posture. If due to ruptured abscess, source of abscess is not sought for unless condition of patient is fair. No irrigation of pus derived from tissue or blood. He gives salines by rectum and occasionally subcutaneously.

John Young Brown, St. Louis, reports about 50 cases with a mortality of about 15 per cent. He operates on all cases, unless suffering from profuse general sepsis. He deals first with the primary source of infection, then "stabs" above the pubes, puts a large glass tube in the cul-de-sac and places patient in an exaggerated Fowler position. He has stopped irrigating and handles the viscera as little as possible. He believes that the hitherto high mortality rate has been largely due to the attempts of surgeons to do too much in cases of widespread peritoneal infection.

J. B. Murphy, Chicago, has a series of 24 operations, with only 1 death. He protests against irrigation and handling of viscera. His method consists of tube drainage in pelvis, Fowler position, proctoclyses, and antistreptococcic serum.

Thomas B. Noble, Indianapolis, employs a similar technic. He says that one can never tell what case is hopeless. He refuses to operate only when patient is dying and thinks then under local anesthesia some may be saved. He reports 5 cases operated on with only 1 death.

Byron Robinson, Chicago, also employs incision and drainage, with incision into the colon for relief of distending gases. He says: "I operate on any peritonitis which does not appear to check by anatomic and physiologic rest."

Now let us analyze these replies:

To my first question seventeen said "Yes." Seven gave affirmative replies, with qualifications. One avoids operation if possible.

Question 2 developed the statement by fourteen writers that no contraindication to operation should be considered except the moribund state. Nine gave symptoms which virtually imply the same condition, while two did not answer the question.

In answer to Question 3, statistics were supplied by twelve, a few of which were estimated. There were reported 374 cases, with a total of 232 deaths. This gives a total mortality of a fraction over 62 per cent.; a high death rate to be sure, but it does not bear out the opinions that all will die, no matter what treatment is employed.

My fourth question pertained to methods, and it developed that 15 were in favor of irrigation, while 10 opposed it. The Fowler position was advocated by a total of 17. It was not mentioned by the others.

The answers to my fifth question tallied very closely with replies to my second.

In going over the methods of treatment we find that operation is advocated in nearly every instance as the only rational procedure. The technic, however, varies considerably; prognostic opinions likewise. We find here the optimist, who believes that nearly every case ought to be saved. We are not without the pessimist, who thinks all will die. And, as usual, we have intervening shades of opinion. Is there anything in these reports to account for such variance in belief? Let us question them still more critically.

Points on which there is no contention are: Free drainage and the Fowler position. True, the methods of drainage are somewhat at variance, but all are primarily agreed on its use, and all place it in the pelvis, and in other regions as indicated. Irrigation is favored by the majority, but those who use it seem to have the highest mortality. They report, altogether, 252 cases with 199 deaths. This is a mortality of 79 per cent. Where irrigation was not employed 92 cases were reported, with a total of 18 deaths—a mortality of less than 20 per cent. This looks significant.

I am aware that there is liability to error in these figures. Other factors may have figured in the cases to some extent. Still, the difference in death rate is so striking that it challenges our attention, and needs an explanation. I know that some operators report success with irrigation. Levings[3] recently reported 10 cases operated on in 10 months, with 9 recoveries, and in each case he flushed the abdomen with acetone solution, 1 to 10,000. Note, however, that he applied it *through the drainage tubes,* without handling the viscera.

Among English surgeons I find C. A. Ballance[3] warning against the practice of irrigation and handling the viscera. He thinks the heavy death rate in the past has been due to these methods. Also, in the Erasmus Wilson Lectures on peritonitis, Dudgeon and Sargeant,[5] who investigated a series of cases at St. Thomas' Hospital, report 119 cases of diffuse peritonitis resulting from perforations in appendicitis. Of this number 100 were treated in the ordinary way by lavage with sterile water or salt solution; 80 of the patients died; the remaining 19 were sponged locally, and drained without flushing, with 10 deaths. This gives 80 and 53 per cent., respectively, for the two methods. None of the cases were selected, save that a few of the latter were given this conservative treatment because they seemed hopeless. The writers unhesitatingly endorse the method which gave the most satisfactory results.

There is another element in these reports which undoubtedly modifies statistics. I refer to the laxity in the use of the term "general" peritonitis. Senn directed attention to this in 1897. One or two of my correspondents have emphasized it, and I find a note of warning in the excellent lectures above referred to. Every case of peritonitis at first is local. When it is not limited by adhesions these writers[5] prefer to call it "diffuse," the term "general," or "universal," being reserved for cases in which the entire peritoneum is involved. They claim, also, that no accurate opinion can be formed at the time of operation, as to whether a case is diffuse or general.

If it be true that the method which omits flushing and handling and sponging gives the best results, as it seems to do, what are the reasons therefore? Let us examine the processes by which nature combats the infection. They are:

1. A serous exudate.
2. A fibrinous exudate.
3. Hyperleucocytosis.
4. Route of absorption.
5. Anatomic and physiologic rest.

1. The serous exudate serves to dilute the toxins of the infections and perhaps has a tendency to neutralize them with antitoxins. We may assist in this dilution by flushing, but there is a better way. Water introduced slowly by rectum will accomplish the purpose without traumatic effect on the peritoneum. It also favors elimination. Murphy[6] says eighteen pints of salt solution may be introduced into the rectum in twenty-four hours, and retained if introduced slowly under low pressure (one foot elevation). This I consider a most important element in treatment.

2. We all know something of the benefit to be derived from a fibrinous exudate. It tends to wall off the infection and to change a diffuse into a circumscribed inflammation. It helps to protect the endothelial coat

from the destructive effect of toxins. A blistered or denuded peritoneum is a distinct menace to the life of the patient for the reason that it allows absorption to take place directly into the blood stream. Dudgeon and Sargeant[6] observed that the *Staphylococcus albus* was the first organism to appear in peritonitis and the last one to disappear. It was always associated, when present, with a fibrinous deposit. They believe it has an influence on the formation of fibrin, as well as with the attraction of leucocytes into the field. The leucocytes produce a turbid appearance in the fluid present, and the surgeon has been trying all along to remove this creamy substance, which really is nature's bodyguard, fighting the infection. The point is, let the fibrinous exudate alone. How differently from the recommendation made to the French Surgical Congress by Demons[7] a few years ago, viz., to scrape the entire surface of the intestine.

3. Hyperleucocytosis, generally, is an expression of the natural resisting power of the individual, as compared to the amount and character of toxemia present. It is favored by such measures as conserve the patient's energy, and the fact that leucocytes are present in the exudate in large numbers is no indication for flushing. You can not remove pus from the peritoneal cavity without breaking up the fibrinous deposit, uprooting the endothelial cells and producing multiple atria of infection. Pus goes in the line of least resistance. Remove the tension, give it an outlet and leave the rest to nature.

4. Robinson[8] and other observers have demonstrated that the place of greatest absorption is the diaphragmatic pleura; also that absorption takes place primarily through the lymphatics, chiefly in the direction of the thorax. Muscatello, in his experiments on dogs, showed that the upright position retarded but did not prevent absorption by this route, and, furthermore, there was no evidence of absorption by any other channels. The abdominal organs after five and one-half hours contained none of the reagent used in the experiment. This explains the efficacy of the Fowler position after operation. Absorption is delayed and time is gained for the patient, and time is an important element in the fight.

5. Nature enforces rest by inflicting the patient with pain. The normal peritoneum is practically without pain sensation. When it is inflamed the pain is terrific. As a result the diaphragm and other muscles are fixed; the parts are placed under enforced rest. Robinson[8] says that the diaphragm acts as a force pump, sucking up the fluids from the peritoneum during respiration, and forcing them onward through the lymphatics. If this be true, rest is greatly to be desired. It also tends to limit the spread of infection throughout the peritoneal cavity, for it must be remembered that diffuse inflammation is not of necessity general.

To sum up, I believe the indications for treatment are:

1. Early operation—and it must be remembered that this implies an early diagnosis. Do not wait for shock, which is a symptom of overwhelming infection. Learn to recognize the early symptoms as stated by Murphy:[9] "Pain, nausea and vomiting, localized tenderness, circumscribed flatness on piano percussion, elevation of temperature and hyperleucocytosis, in the order named." I repeat it, operate early.

2. Method—simple incision, with simple drainage, placed in pelvis and such other fossæ as seem to require drainage. Perforations should be closed, and appendix removed if it be the offender, provided these things can be done without too much handling of viscera.

3. Fowler position to retard lymphatic absorption.

4. Physiologic salt solution by rectum, one and one-half pints every two to four hours for twenty-four to forty-eight hours.

5. Antistreptococcic serum in suitable cases in hope to combat the effect of toxins absorbed.

TREATMENT OF CONGENITAL DISLOCATION OF THE HIP.

WITH REPORT AND EXHIBITION OF CASES.*

PARK WEED WILLIS, M.D.
SEATTLE, WASH.

It is not my intention to give an elaborate paper on the treatment of this disease, but simply to go over briefly the methods used in these cases which are reported. The fact that it is necessary to wait for many months, or even years, before the final result is known, and the further fact that only a few years ago this disease was relegated to the surgical waste basket as being incurable, places our knowledge of the result of treatment of it at the present time in a more or less uncertain condition.

Many objections have been raised against the manipulative method as practiced by Lorenz and his followers. Serious complications, such as paralysis, fracture of the bones, rupture of the blood vessels, gangrene, and loss of limb, have been too frequent; and the final results are not by any means perfect. Ankylosis may occur, complete relapse is comparatively frequent, and anterior transposition is so common as to be almost the rule.

The operative technic here followed has been that practically as given by Royal Whitman[1] and J. Jackson Clarke.[2] The tissues on the inner side of and anterior and posterior to the joint are, in turn, stretched until sufficient relaxation for reduction is produced. This result has usually been accomplished when the trochanter can be drawn down to Nélaton's line. Reduction is attempted by forced abduction of the thigh, which is at the same time completely flexed on the abdomen and rotated inward. Either the hand of the operator or a wedge may be used as a fulcrum behind the trochanter. After reduction the anterior fibers of the capsule are stretched and the plaster cast applied. Only in an easy case, however, would the operation be completed at one time.

The structures with which we have to deal in these operations are frail, while the leverage is great; consequently special care is necessary to avoid injury. After a moderate amount of manipulation of the tissues and a few gentle attempts at reduction, the hip is placed in a cast in a position of abduction. After two or three weeks, the cast is removed and another attempt made at reduction. At this time, the adductors will be found well relaxed, and most of the manipulations will be required on the posterior and anterior muscles, especially the tensor fascia femoris. The same method, however, as previously practiced, is repeated again at this time. If, after three or four attempts, reduction can not be accomplished, it is undoubtedly wise to resort to open incision. When reduction has been secured, the cast is changed about once in two months, or more frequently if much soiled or broken, and at the time of such a change a radiograph is taken, and the hip gently moved in different directions, avoiding adduction. This gentle, repeated manipulation should eliminate almost completely such complications as result from fracture of bones and laceration of the soft tissues. The frequent dressing, with *x*-ray picture, keep the surgeon posted as to the progress of the case, and the tissues about the joint are also kept in better condition. On account of the frequency of relapse, treatment in the cast, even in favorable cases, is continued for at least one year after final reduction. The following cases are reported:

[2] The Practitioner, March, 1903.

Case 1.—R. R., female, born in February, 1901, began to walk in August, 1902, when the limp was first noticed by her parents. In April, 1903, the child had empyema, and after recovery from this the limp was more noticeable. She came under my observation in October, 1903, with congenital backward dislocation of the right hip. The shortening was three-quarters of an inch. My friend, Dr. Joseph C. Bloodgood, of Baltimore, who has given me much valuable advice and assistance with all these patients, had charge of this one, and, with my assistance, manipulated the hip for twenty minutes without securing reduction. A cast was applied with the limb in abduction. This patient was treated until the present time under the direction of Dr. Bloodgood, and it was at his suggestion that the repeated gentle manipulative method was used. In January I manipulated this hip the second time under anesthesia and very easily secured apparent reduction. The femoral head could be plainly felt anteriorly, and the hamstring tendons were contracted so that it was impossible to straighten the leg. The *x*-ray, however, cast a gloom over my hopes by portraying the fact that the bone was really in a position of anterior transposition, where it has since remained. The cast was changed about once in two months until January, 1905, when it was replaced by an external hip splint, holding the leg in slight abduction. In July, 1904, the cast was removed and the patient placed in bed, with slight extension, for one week. She is now walking, without any support, a portion of the time, but with a moderate limp. This limp may be partially habit, as the splint is still worn most of the time. There is free movement, with about three-eighths of an inch shortening.

Case 2.—F. C., female, born in September, 1899, was referred to me by Dr. L. R. Dawson in June, 1903, with the diagnosis of double backward congenital dislocation of the hips. In October, 1903, Dr. Bloodgood assisted me in manipulation of her left hip, and, although the reduction was not accomplished, a cast was applied with the limb in abduction. In January both hips were manipulated, the left giving clinical signs of reduction, while the right was still unreduced. Early in February an anesthetic was given, and the left was found in its former position of backward dislocation, and I was unable to replace it, although apparently the muscles were thoroughly relaxed. At this time the right hip was reduced with audible thud and jerk and gave other clinical signs of reduction. The *x*-ray showed that it was in perfect anatomic position, and it has remained so until the present time. The cast was applied with both thighs in abduction, and again in March an anesthetic was administered and the left hip again apparently reduced after great difficulty. The cast was removed, however, two months later, and it was again found in a dorsal position, and three or four efforts after this failed to change its location. In October, 1904, after performing tenotomy of the adductors and the tensor fascia femoris, and still failing to accomplish reduction, I operated by open incision, using Lorenz's modification of Hoffa's method. On opening the capsule, practically no fluid was found: the head of the bone was eroded, the neck was at right angles to the shaft, the ligamentum teres absent, and the capsule contracted at the head of the femur. It was impossible to find the joint cavity until a more careful examination revealed the fact that the capsule was stretched across the acetabular cavity and firmly adherent around its rim. The capsule was freed by dissection from its adhesions to the acetabulum, which was found to be very shallow and contained little or no débris. The bone was replaced and one or two catgut stitches placed in the capsule and the external wound closed without drainage. The wound united, apparently without infection, although the union was slightly delayed in one part on account of the stitches not being near together, causing a small superficial granulating surface. One month after this operation, the head of the bone was again found in a dorsal position, but was very easily reduced. It was then put up with increased abduction and has since remained in place, while the abduction has been gradually decreased.

In February, 1905, a radiograph showed an apparent separation of the lower part of the left sacroiliac joint, and also a change in the ilium opposite the acetabulum, which looked very much like a fracture, but was not so considered by Dr. C. H. Thomson, who has taken most of these radiographs, although he thinks the bone was pushed in a little. This occurred after a manipulation so gentle that the child, without anesthesia, did not cry. The cast was removed in March and the patient kept in bed and the left hip manipulated to try to loosen the adhesions. In May she was allowed to walk, with a brace for slight abduction of the right hip. When the first apparent reduction was obtained by the manipulative method, it was evidently with two folds of the capsule between the head of the bone and the cavity, and there is a question in my mind as to whether these manipulations and the replacing of the bone in that condition did not tend to cause the adhesions of the capsule which were found. At the present time, the right hip has good motion and is apparently in good position. The left hip is in good position, but with limited motion with slight abduction and one-quarter of an inch shortening in comparison with the right. The stiffness will probably disappear, as there is no evidence of bony ankylosis.

Case 3.—L. K., female, was born in October, 1901, and began to walk October, 1903, and was then noticed by the parents to have marked lordosis and a peculiar gait. In June, 1904, the late Dr. F. H. Coe saw her and made a diagnosis of double backward congenital dislocation of the hips and referred her to me for treatment. She was operated on by the manipulative method under anesthesia July 11. The right hip was apparently reduced after manipulation of forty-five minutes. The left one was reduced to anterior transposition after manipulation of about thirty-five minutes. These were comparatively easy to reduce, but still easier to displace. The *x*-ray showed very imperfectly formed acetabular cavities, and also showed that neither reduction was anatomically perfect, but both anterior and a little above. In both cases the head of the femur could be felt in front, and the ham-string tendons showed apparent shortening. Even with this apparently moderate manipulation, there was considerable swelling and ecchymosis about the vulva. September 6, the cast was changed and the left hip again found on the dorsum, and an apparently perfect reduction was obtained, and it still remains in that position. The right was probably in a supracotyloid position and was brought down on a level with the socket, but could only be kept there by bringing the thigh above a right angle with the abdomen with extreme abduction. At the next dressing, and since that time, it has been found in a position of anterior transposition. This patient is still wearing a cast.

Case 4.—C. C., female, aged 17, born in Seattle, after difficult instrumental labor, came under my observation in October, 1903, for congenital dislocation of the left hip. There was shortening of 2¾ inches, which could be reduced to 1¾ inches by traction. Abduction was very much limited and there was marked tilting of the pelvis. Her only symptom was a moderate but characteristic limp, which was lessened by the use of a cork sole. She seemed rather proud of the fact that she could kick higher with this foot than with the other. No treatment was advised. She was married a few weeks later, and no further reports have been obtained.

Case 5.—M. M. O., aged 23, married, came to me in June, 1904, about five months' pregnant. The history was that she tired easily about the hips and had more or less pain in the right. This trouble dated back four years, when, after riding astride a horse, she felt a catch in her right hip. Previous to that time, there was no pain or discomfort, although, she said, she had always walked like a duck. On examination, a double backward congenital dislocation was found, and this diagnosis was verified by the *x*-ray. The nature of her deformity had not been previously discovered. She was delivered October 1, at full term, after ten hours' easy labor. Her version of her present condition is that her right hip tires more easily, is more painful and has increased in size since the birth of her child.

Results in the treatment of this disease necessarily vary greatly with the age and condition of the patient. These eight hips here reported give two anterior transpositions with three anatomically perfect results, one of which was obtained by open incision and resulted in limited motion, which, however, may not be permanent, as the treatment can not be considered complete in any of the five hips treated. The permanent functional results, which are of the greatest importance, will only be known months, or possibly years, later. The three adult hips, in which no treatment was advised, showed a comparatively small amount of disability. The method here used of repeated, gentle manipulation, has the advantage of little danger, and, in case of failure to maintain and accomplish reduction by this process, the patient is better prepared for the method of open incision, which must be resorted to in a certain proportion of cases in order to accomplish the best results.

DISCUSSION.

Dr. S. J. Hunkin, San Francisco, thought it the duty of every surgeon to replace the hip joint in the quickest and easiest manner possible, let that method be according to the Lorenz plan, the Hoffa maneuver, or by an open incision. Dr. Hunkin considered that often it is better surgery to make an incision, open the capsule and put the head of the femur into the acetabulum under the eye, than to make severe traumatism and excessive ecchymoses, in a blind attempt. There is usually not so great difficulty in young children in getting the head of the femur to the site of the acetabulum as there is in maintaining it there. Often there is no acetabulum or only a small, shallow, smooth, slightly concave surface, and under such conditions, one may have to go back to the old Hoffa open operation, and scoop out a cavity big enough to hold the head. Dr. Hunkin remarked that the last speaker seems to have had some difficulty in preventing posterior reluxation, and he thought that due to the position maintained in the splint—the leg must be abducted and maintained at or posterior to the horizontal plane of the trunk. From this position an anterior transposition may result, but not a posterior reluxation. In addition to the usual splint Dr. Hunkin makes a later splint, open at the side and removable, which the patients wear at night for a year after they are free by day. This forces the limb into the extreme postoperative abducted position, for twelve hours a day, and a smaller percentage have relapsed since he has followed this plan.

Dr. DeForest Willard, Philadelphia, said that Dr. Willis' results correspond very closely with those of others who have attempted this operation. A certain number of young children will be benefited and a considerable number will be found after a time in a condition of ante-transposition. Some will be failures, which is the experience of all who have attempted it. If Dr. Willis' plan of gentle manipulation can replace the more forcible one it will be a great advance, but many accidents had resulted. As to the anterior transposition, especially in children over 7 or 8, where the bone has been put into a new position after the muscles have accommodated themselves to the former position, even if it be a dorsal one, Dr. Willard does not believe these cases are benefited in the least degree. They may walk with a little less lordosis, but they have not as good balancing power. They can not perform as good labor as if the head of the bone was lying in its original position. In the latter case they may walk badly, but they are stronger and better prepared for their work, which is important, especially with men. As to the open operation, it will likely result in a stronger hip, although we are very likely to have ankylosis. There is a danger in the open operation about which we should warn the patient in advance. As to the prognosis; from the newspaper reports the public expects that all these cases are going to walk as well as a well individual, but any surgeon who gives this idea to parents is unwise. We must be cautious in our prognosis, and we should not attempt the operation in too young children. Dr. Willard said he had not had much trouble in getting the hip back to the site of the acetabulum, where there is any acetabulum, but the majority of cases have none. The parts are all malformed and one can not make the head remain in position. It may stay there six months or two years, but some time or other the child must walk, and then comes the time when it will slide out of the acetabulum. It is simply a question of having a normal acetabulum before reduction should be attempted. If we have only a tea saucer, instead of a teacup, it will surely slide out again, and there is where the great difficulty arises.

Dr. C. O. Thienhaus, Milwaukee, Wis., said that while it has been generally accepted by the writers on congenital dislocation that in cases in which the retention after the bloodless reduction is difficult or the reduction impossible, a hypoplasia of the acetabulum is the underlying cause. Deutschlander has recently shown and proved by experiments on animals that in most of the cases of congenital dislocation we do not find a hypoplasia of the acetabulum, but a hyperplasia of cancellous and fibrous tissue within the acetabulum. This cancellous tissue, which can not be demonstrated by Roentgen rays, is one of the causes of difficulties in reduction by the Lorenz method and for retention of the head of the femur after the reduction has been accomplished. Dr. Thienhaus did not agree that the bloody operation will be the operation of the future. All those who are now the ardent advocators of the bloodless method, as Lorenz, Hoffa, Mickulicz, Lexer and others, tried the bloody methods of reduction first, but after a large experience taught them that by using this method we are very liable to have stiff joints as a result, and after they were convinced that the results obtained by the bloodless reductions were far superior to those obtained by the bloody methods, they accepted it as a law in all cases first to try the bloodless method of reduction, and after two or three attempts by this method have proved unsuccessful or the functional results obtained unsatisfactory, then to use the bloody method. If cases are taken at a suitable time, that is, from the third to the fifth year, surgery can show from 60 to 80 per cent. good functional results.

Dr. Harry M. Sherman, San Francisco, said that it certainly is a novelty to say that a congenital dislocation can be reduced by a gentle manipulation repeated a number of times, when it can not be reduced by violent manipulation at one sitting. Dr. Sherman said that it was as difficult for him to understand how Dr. Willis puts the femoral head through the narrow part of the capsule as it was difficult for him to understand how anyone can do it by violent manipulation after the method of Lorenz, excepting in a very small percentage of cases. The proposition is the old difficulty of making the femoral head pass the opening in the neck of the capsule. The former is invariably larger than the latter. The opening is smaller than is the bone which has to go through it. About the highest percentage of satisfactory anatomic repositions which can be expected is 10 per cent. with the forcible manipulation of Lorenz. Dr. Sherman still believes that the method which is right is the one which definitely does what the operator sets out to do. Dealing with a dislocation, the object is to reduce it. He said he could not accept any method as satisfactory which fails to reduce, and he did not see any reason for temporizing with a half-way measure when a real anatomic reduction can be accomplished by means of a small incision, an incision which shall go anterior to the tensor vaginæ femoris so as to avoid cutting off its nerve supply, and which shall cut no muscular tissue, and lying in its original position. In the latter case they may capsule of the joint. Through this the head can be put into the acetabulum and the reduction will have been accomplished. Dr. Sherman wanted to hear Dr. Willis' explanation of how he accomplishes the feat of making the camel go through the eye of the needle.

Dr. E. H. Parker, Portland, Ore., said that he has under his care a family in which the grandmother, aged 60, weighing 200 pounds, has congenital dislocation of the left hip joint, which has given no trouble all these years, although she has raised a large family. She walks with a limp, but gets along nicely. Her oldest daughter has congenital dislocation on the same side, but her granddaughter, a child of 10 years, is perfectly formed.

Dr. James E. Moore, Minneapolis, protested against the misnomer, "the bloodless operation." He declared it the most bloody and the most unsurgical procedure that he had ever had anything to do with. The operation of the future will be the open operation and not a mutilating one, which does not give the surgeon the opportunity to see what he is doing. There will be no more stiff legs and deformed children. The Lorenz method leaves the patients in worse condition than they were before.

Dr. S. C. Baldwin, Salt Lake City, said that he believes that Dr. Sherman is very near to the proper solution of the problem. There is in all these cases a malformation of the head and a filling up of the acetabulum. The head is so badly shaped that it will not stay in position. Dr. Baldwin said that the Lorenz operation is a very bloody operation, and that he does not believe that we should resort to it to such an extent as to cause a severe ecchymosis. The Hoffa operation does too much damage to the soft tissues. The operation of the future will be done in the general way Dr. Willis speaks of. After cutting down with a small incision, the head of the bone will be put in position. With all precautions there will at times be suppuration. It is not possible to avoid this in every case, and consequently an operation by the manipulation method without any great damage to the soft tissues is the best thing to do. Dr. Baldwin believes that the coming operation will be the Sherman operation.

Dr. A. J. Ochsner, Chicago, expressed the fear lest the drift of this discussion, being entirely against the manipulative method, should leave the wrong impression on the minds of those who have no experience with this operation. A great amount of harm has been done in patients not properly selected, especially as regards the age of the children, but this is not the case where the proper selection is made. Dr. Ochsner said that he could speak with authority because he has seen some twenty cases properly selected in which the dislocation was proved by the skiagraph before the treatment was begun and, after the treatment was completed, the skiagram showed that the dislocation had been reduced. Moreover, in one case of a double dislocation of which there is a skiagram, he has seen the specimen after autopsy, the patient having died three years later, after walking perfectly for one and a half years. The skiagram showed absolutely that there was a dislocation before this treatment was commenced, and as shown by the specimen, it was absolutely reduced; consequently this shows what can be done in properly selected cases. Dr. Ochsner said that he had never operated by the manipulative method. All of the cases he has observed before and after the treatment were operated on by his brother. In young children, to the age of 5 or 6 years, this method should be employed by a competent surgeon. If a surgeon knows how to perform this operation properly and chooses the proper kind of cases, this method will produce many excellent results which will be functionally and anatomically satisfactory.

Dr. P. W. Willis replied as to the position of one of the hips shown, of which it was said that this, being anterior to the plane of the body, would tend to cause a posterior dislocation. This hip was reported as being anterior and was brought forward purposely in order to bring the head of the bone back nearer the acetabulum. Some say that the open incision is a surgical procedure. After reading reports and hearing Dr. Willard's remarks, Dr. Willis still considers that this intensely surgical procedure gives us stiff joints and crippled patients. It does not matter whether the procedure is surgical or otherwise, providing the desired result is obtained. One speaker says: "Make a very little opening; what harm can it do?" Enough germs can get into a small opening to ruin both hips. A penetrating wound is one of the most dangerous. If an incision is decided on, make a large one to place the head in position. It is not everything, however, simply to open the joint. The long muscles are shortened, and it is necessary to stretch these and other structures in order to put the head into place. The reduction of the head is often easy, but to keep it there is the point. Even with open incision Dr. Willis' cases do not always stay there. According to the pathology of this condition, at birth the head of the bone is very close to the acetabular cavity, and in the majority of cases there is a large short capsule without contraction. As the child begins to walk, however, the head of the bone passes away from the socket and in time the capsule may be drawn out until it presents that contracted condition shown by Dr. Sherman. When this takes place the open operation is indicated. Good functional results are what we are striving for, and in many instances these can be obtained by the manipulative method. Dr. Willis disclaimed responsibility for the term "bloodless;" he did not refer to it in his paper. The operation is not bloodless, and even with great care there is ecchymosis. The manipulation should be as gentle as possible.

THE CURE OF HERNIA.*

HENRY O. MARCY, A.M., M.D., LL.D.

BOSTON.

Three decades have nearly passed since I first obtained respectful attention from the Section on Surgery of the American Medical Association, when I announced a new method for the cure of hernia.

This method was based on the reconstruction of the inguinal canal to its normal obliquity. This was rendered possible only by a free dissection of the parts, the resection of the redundant peritoneum and closure of the deeper structures beneath the cord. The cord was then replaced and the external structures united. The wound was sealed with collodion. The suture material was catgut, furnished me from Glasgow, Scotland, by the instrument maker who prepared ligatures for Mr. Lister, after his formula. The buried animal suture was the inspiration of the moment, born of necessity, in the closure of a strangulated inguinal hernia. This was in 1870. A long series of histologic experimental studies on animals was undertaken to determine the results of buried suturing, and the technic of the operation was carefully worked out in detail.

The crucial experience of the years has naturally resulted in very many modifications of technic, by many surgeons. The fundamental factors of the operation, however, must ever remain the same, since they are based on the physiologic plan of normal development.

The obliquity of the inguinal canal was more or less recognized by all the early anatomists, but, so far as I am aware, had never been emphasized, or even referred to, as the reason why hernia did not take place in the normally developed male. The reason that hernia is not more common is dependent on the fact that the intra-abdominal pressure, acting on the normal structures, brings this force to bear at right angles to the long axis of the canal and hence, the greater the pressure, the more closely the walls of the canal are approximated.

This valve-like construction of the canal is brought into play in the human organism only in two other instances: the entrance of the hepatic and pancreatic ducts into the intestine, and the point of entrance of the ureters into the bladder.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The operative procedures for the cure of hernia are absolutely dependent on the use of buried sutures, since without them the reconstruction of the inguinal canal to its normal pattern is impossible.

More or less imperfect attempts were made to accomplish this, without recognition of the principle, by many of the early operators. One was the so-called invagination process, in which an instrument was firmly thrust, from below upward, through the canal, returning the peritoneal pouch, thereby carrying the cord upward, and fixing it in position by the introduction of wire sutures from below; more commonly they were brought out externally and twisted over some foreign material to protect the skin. Infection usually followed, and suppuration was welcomed because of the belief that the infiltration and induration, which supervened, greatly aided in strengthening the surrounding parts.

This method was improved on by the distinguished surgeon, John Wood of London, and his still well-known method of suturing by the implantation of wire, without the plug, in the canal. He became very dexterous in this operation and reported a large number of cures. Without especially emphasizing the reason, the result attained was the lifting of the internal ring and the cord to a much higher plane in the abdominal wall.

At an earlier period, great success was attained, especially by the surgeons of France, in the cure of hernia by boldly making an open wound, excising the testicle and cord and either closing it by means of sutures or, perhaps more commonly, by treating it as an open wound and allowing it to granulate from the bottom. This latter method was emphasized, since it was believed that the cicatricial mass resulting gave a stronger abdominal wall. It is extremely probable that these observations were correct, since the open-wound method and through and through suturing gave a wound almost necessarily septic, with a very imperfect result. Even now it does not appear possible that improvement could have been made on the older measures, until the scientific demonstration of wound infections, and, as a consequence, how to avoid them became the basis of a new technic. This must ever remain to the immortal honor of my great master, Lord Lister.

The object of this paper, however, is not a historical résumé, but rather to ascertain if, even now, we have arrived at a general consensus of opinion as to the measures which are essential and the operative procedures which should be adopted. At the outset let it be emphasized that, while the general measures of restoration may be agreed on, it is a well-known principle of applied mechanics that the operator best attains results by the means with which he is most familiar. While there are comparative means of excellence and the result attained good, the methods employed should never be considered absolutely faulty unless they fail to accomplish the end desired.

To make myself more clear, the first object of eating rice is the transposition of this nutritious article safely into the stomach. The Chinaman would declare that his chopsticks were used far more advantageously for this purpose, and besides that nine-tenths of all the rice eaten is expeditiously carried into the mouth by these simple instruments. Few Europeans or Americans, for this reason, however, would be content to abandon the fork or the spoon. For an equally good reason I should consider relatively immaterial the character of needle or other instruments employed. This view relegates as comparatively unimportant a very considerable number of so-called methods which are prominently labeled by the name of the author.

Beside the anatomic reconstruction, the one essential is the absorbable, animal suture. This may consist of properly prepared catgut, but for many reasons the carefully selected tendons from the smaller varieties of the kangaroo are much to be preferred. When prepared to retain their strength for only a few days—and they permit of ready absorption—they are ideal. They must be applied, however, so as to hold the reconstructed structures in coaptation with as little injury as possible and without constriction of the enclosed parts. Too much force applied is an almost universal criticism.

CAUSE.

When we remember the late period of development in fetal life, and that by second thought, as it were, Nature changed her plan and decided to remove the testicles from within the abdomen; and when we study the method by which she accomplishes this object, we not alone find the reason why such a large percentage of males suffer from hernia, but may wonder, rather, that more are not subject to this infirmity. The spermatic cord for the transfer of semen from the testicle to the seminal vesicle is not alone enormously lengthened, but its double system of accompanying vessels must be maintained. Organs of considerable size must be transposed to an entirely new relationship and they must carry before them a prolongation of the peritoneum as a proper protecting envelope. This dainty enwrapping structure becomes blended with the vas deferens and vessels, making up the component parts of the cord. This structure must lie at easy physiologic anchorage and yet the abdominal wall must not be weakened by its passage.

Defective closure of the internal ring is not rarely apparent, even in men who are not afflicted with hernia. Cloquet came to the conclusion, after 500 dissections, that the internal ring was so open that a depressed spot in the peritoneum marked its site, and this has since been called after him, the infundibular process of the peritoneum. In the normal subject, however, this is produced only by pulling on the cord, when, of course, its attachment will deflect outward the abdominal peritoneum. My own studies lead me to believe that the internal ring is often unduly open, owing to an incomplete development, and that this is by far the more common cause of hernia, even in those patients in whom this infirmity develops late in life.

By a singular, wise provision of Nature, the intestinal contents are so distributed that the law of gravity is minimized in its hydrostatic pressure. This, however, is necessarily greater in man, as an upright animal, on the lower portion of the abdominal restraining wall, than in the quadruped, and man, therefore, is much more likely to have hernia of the inguinal canal than animals.

Given a slight weakening of the internal ring in man, producing a dimpled depression, and multiply the intra-abdominal force constantly called into play by the time element of years, and we can easily see that there may come a period when these structures, little by little, may yield and form an opening for the lodgment, or escape, of a portion of the abdominal contents.

The man may not have been seriously incommoded until a late period of life. At last a sudden yielding of the external barrier gives evidence to him of the disability, which on this account has from time immemorial been called rupture.

The imperfect completion of the normal process following the extrusion of the testicle is often noticed in early childhood, when a decidedly open canal may be demonstrated, but Nature usually safely finishes the process during the early years of development; this is similarly noticed in umbilical hernia.

WHEN SHALL WE OPERATE?

The preceding discussion leads us to the proper consideration of the class of cases in which operation should be advised. During the tentative period of operative study, naturally all surgeons were more conservative. Since it has been shown that the operation is practically without risk to life, there has been a steadily increasing opinion favorable to operation. Contrary to the views of even a few years ago, at the risk of being dogmatic since the limits of the paper do not permit discussion, we may safely determine that the operation is advised on all children in whom there is difficulty in retaining the abdominal contents.

In children, my personal experience has been large and it has proved a profitable field of study in the elucidation of the fundamental causes of hernia.

Since the methods already referred to and which are to be more specifically described a little later have their simplest application in childhood, they are here to be especially commended. It is true that the surgical manipulation is as dainty as that on the eye, and, as a consequence, is as esthetically admired, but the collodion seal, as a sure antiseptic application, robs the subsequent treatment of its chief difficulty and danger. Were there not a more serious side to the consideration of the more commonly applied antiseptic dressings, by which the little patient is made an intense sufferer, this legacy of conservatism of the past would assume a most grotesque aspect. Some time since I saw one of these little martyrs of so-called modern science enveloped with swaddling clothes like a mummy, held in place by a plaster of Paris, fixed bandage, enveloping the little sufferer from the knees to the navel, and this in a children's hospital holding a first place in the greatest city of America.

A recent English writer tabulates several hundred operations on children, and ascribes a large share of his success to that which I unhesitatingly call a most cruel and injurious procedure.

All know that repair processes in young animals go on much more rapidly than elsewhere. The straining from crying is perhaps the greatest danger with which we have to contend. The happy child cries least, or not at all; and how can we hope to avoid these expressions of pain induced by such inquisitional surgery? The young adult, otherwise healthy, demands relief at our hands from a lifelong infirmity—an infirmity which debars him from athletics, from Government service, and from many of the more active and lucrative departments of life's vocations.

In all the older periods of life the hernial contents may not be safely and easily retained by external supports: in all the more grave and disabling conditions, where life's vocations are seriously limited, and pain and disability are present. There is a small class of cases in which the transposition of the abdominal contents is so extensive as not to permit a safe return into the contracted abdominal cavity, but this class is an extremely limited one and even there measures may be devised, preceding surgery, to make the operation usually a safe one.

OPERATIVE PROCEDURES.

In discussing the essentials, these should be reduced to the last analysis. Asepsis must be maintained, the contents of the hernial sac examined and reduced. The sac itself, if in any considerable degree pathologic and enlarged, is dissected to its base, evenly sutured, under slight tension, in the line of the axis of the canal and resected. The resilience of the peritoneum is quite sufficient to cause it to present an intra-abdominal smooth surface.

The suture best adapted for this purpose is a fine, double, continuous one, care being taken to coapt and not to constrict the included portions. The problem of restoration of the posterior wall of the canal is not so simple, owing in large measure to the deformed and weakened conditions found. Sir Astly Cooper, so far as I know, was the first to point out the singular increase of strength and reinforcement by Nature of the tendinous expansion of the transversalis muscle. Incorporated fibers of the muscle itself are sometimes seen to extend above the internal ring. When this condition exists the internal ring may be said to consist of a slightly ovate opening in the transverse muscle. One certainly finds Nature's strongest bulwark of the posterior wall of the canal to consist of these structures.

In a hernia that is at all pronounced, however, these are so weakened and deformed that they do not furnish a secure reinforcement for the reconstructed internal ring and posterior wall of the canal. In order to give additional strength, I have usually found it wise to include the posterior fibers of the conjoined tendon which are coapted with the posterior fibers of Poupart's ligament. In almost every instance in this way a safe, secure, firm posterior wall of the canal and internal ring, reformed high up on the cord posteriorly, may be constructed. It leaves, as lateral walls, the outer edge of the conjoined tendon and Poupart's ligament.

In other words, this portion of the canal, so far, has been restored in its normal relations and length. It now remains to replace the cord and to restore the divided fibers of the external oblique to reform the external wall of the canal. It may be well, at least for one of comparatively limited experience, to mark by forceps or suture the long, brilliant fibers of the external oblique at the time of division, and then there is an anatomic landmark for their reconstruction. I am in the habit of taking an extra suture through the structures which go to make up the upper border of the internal ring, since I have known a few cases of direct hernia to follow when the structures were unduly weak. This may not be necessary, but I deem it a wise precaution: a single mattress suture is usually the best means of reinforcement.

A third suture, subcuticular, also continuous and of the very finest type of material is taken through the deeper layer of the skin only; care should be observed that the needle does not penetrate the hair follicles or sweat ducts. If applied with proper care and accuracy, the edges of the skin are held in even coaptation. The collodion seal, reinforced by a few fibers of cotton, carefully applied and dried, finishes both the operation and the dressing.

If accurately and aseptically applied, easy, painless primary union will supervene.

Following these processes of repair, a strong, reconstructed inguinal canal is formed of normal obliquity. The intra-abdominal pressure is evenly borne by the reconstructed abdominal wall and hernia is no more likely to return than in the individual in whom the processes of normal development took place.

If the limits of this paper permitted, we would find a most interesting chapter of history in tracing the various modifications of this operation which have been recommended, especially during the last ten years.

Underlying these is a more or less intelligent effort at reconstruction to the normal pattern. The structures involved have been variably manipulated, even to the transplanting of the cord outside of the external oblique muscle. This latter method is, of course, not to be commended, since the structures of the cord are comparatively unprotected in their new relations and, at the best, emerge through a direct opening in the abdominal wall.

To all surgeons familiar with the practical advantages of the absorbable suture, it seems strange that any good operator can still be found using silk as a buried suture. Recently I discharged from the hospital a young, otherwise healthy, man who last December was operated on by one of Boston's chief hospital surgeons for the cure of hernia. By accident the cord was divided and, as a consequence, the testicle was removed. The hernia was cured, but he had had four subsequent operations because of stitch abscess. It became necessary to make a free dissection in order to find and to remove two deep silk ligatures, one of which was still encompassing the cord. The wound was reclosed by buried tendon sutures and the operation was followed by primary union. Instances of this sort are far too common to be considered accidental or ascribed to fault of technic other than the use of improper suture material.

Dr. Maynard of Dedham, Mass., in 1846 gave to the profession, as a surgical dressing, collodion, a discovery made incidentally to his research work in the investigation of gun cotton. The discovery has proved to be of very much greater value than was at first supposed, since its use in septic wounds, then almost invariably the rule, was detrimental rather than otherwise. An aseptic wound aseptically closed by aseptic, buried, absorbable sutures, is kept aseptic by the use of the collodion seal. Iodoform, in solution, inhibits the development of the *Streptococcus pyogenes albus* in the skin. The seal is loosened only by the proliferation of the epidermal cells and is absolutely trustworthy for a week or ten days. Such a seal may be reapplied, but an aseptic wound thus aseptically treated has in this period undergone processes of repair and is beyond the danger of subsequent infection.

The measures here recommended apply equally well to all aseptic wounds in all parts of the body, but they were first used and their values demonstrated in my early operative work for the cure of hernia.

Special Article

IMMUNITY.

CHAPTER XXIII.

PARATYPHOID FEVER.

Two Types of Organism.

In 1900 Schottmüller cultivated from the blood of five "typhoid" patients organisms which differ from the typhoid bacillus in that they attack dextrose with gas formation and are not agglutinated conspicuously by antityphoid serum. Since that time, many similar cases have been reported and two types of the paratyphoid bacillus have been recognized (Schottmüller). Group B causes first an acid reaction in milk which changes to a permanently alkaline reaction in about ten days, whereas Group A causes permament acidity. (Kayser.) They resemble the typhoid bacillus morphologically. These organisms are more closely related to the bacillus enteritidis than to the typhoid bacillus.

The term paratyphoid is justified only because of the similarity of the symptoms to those of typhoid fever.

"Paracolon" Bacilli.

Previous to the observations of Schottmüller, Widal, in 1897, had shown a "paracolon" bacillus to be the cause of a typhoid-like infection, and a similar observation was made by Gwyn in this country in 1898. These organisms are not different from those which are now called paratyphoid bacilli, and the infections resemble the recorded cases of paratyphoid fever. The term "paracolon" should no longer be applied to these organisms.

Methods of Infection.

The disease occurs sporadically or in epidemic form, and bears a close resemblance to mild typhoid-like epidemics which have been noted from time to time, and which, presumably, were caused by eating poisonous meats. One such epidemic of 600 cases was caused in Switzerland in 1878 by the meat of a sick calf; the mortality was 1 per cent. A still older epidemic (1839) is cited, likewise caused by meat. In both instances, the infection eventually was carried from person to person by contact. A recent epidemic in Kiel, proved to be paratyphoid, is assumed by Fischer to have been caused by infected meat, on account of the peculiar distribution of the cases among the patrons of a particular market. Kurth also attributed a small epidemic to either uncooked meat or milk. Fischer mentions an epidemic of 50 cases in East Holstein which probably was caused by the milk of two infected cows. Shortly after the epidemic began the cows died and paratyphoid bacilli were cultivated from the muscles, spleen, liver and intestines. Infected water also may cause epidemics. De Feyfer in an epidemic of 14 persons in Holland, considered that the disease was transmitted through the water of a stream in which the clothing of the first patients had been washed. In another instance, a regimental infection (Saarbrücken) was traced to the discharges of a single soldier, the water supply having become contaminated through a defective water closet.

Characteristics of the Disease.

Paratyphoid, like typhoid fever, is accompanied by an enlarged spleen and many rose spots. Although severe symptoms may be present for a time the course of the disease usually is mild and the mortality is low. The incubation period approximates that of typhoid. In the few cases which have come to autopsy the intestinal lesions have varied from a mild ileocolitis with an intact mucous surface to a condition of superficial ulceration. The involvement of Peyer's patches and the solitary follicles which is so characteristic of typhoid is absent, although these structures may be moderately swollen. The mesenteric lymph glands are not markedly involved and there is little proliferation of the lymphoid or endothelial cells (Wells and Scott). The disease has no specific anatomic lesion.

Occurrence of Bacillus in the Body.

The organisms are found in the blood and various organs, in the rose spots, urine and feces of the patients. Practically nothing is known of the occurrence of the bacilli outside the body. Because of their presence in the stools and urine of the patients, the methods of dissemination and infection doubtless are similar to those concerned in typhoid. The bacillus is said to have a marked resistance to heat, withstanding 60 degrees C. for 30 minutes and not all cells being killed during one hour at this temperature. This may explain the fact that the virus is not always killed by cooking the meat. The organism probably has a wide distribution because of the occurrence of the infection in various parts of the world.

The toxicity of the bacilli depends on the existence of a fixed endotoxin; a soluble toxin is not produced.

The principles of prophylaxis against typhoid also apply to paratyphoid fever, with the addition that in the latter disease the possibility of meat infection must be kept in mind.

The imperfect completion of the normal process following the extrusion of the testicle is often noticed in early childhood, when a decidedly open canal may be demonstrated, but Nature usually safely finishes the process during the early years of development; this is similarly noticed in umbilical hernia.

WHEN SHALL WE OPERATE?

The preceding discussion leads us to the proper consideration of the class of cases in which operation should be advised. During the tentative period of operative study, naturally all surgeons were more conservative. Since it has been shown that the operation is practically without risk to life, there has been a steadily increasing opinion favorable to operation. Contrary to the views of even a few years ago, at the risk of being dogmatic since the limits of the paper do not permit discussion, we may safely determine that the operation is advised on all children in whom there is difficulty in retaining the abdominal contents.

In children, my personal experience has been large and it has proved a profitable field of study in the elucidation of the fundamental causes of hernia.

Since the methods already referred to and which are to be more specifically described a little later have their simplest application in childhood, they are here to be especially commended. It is true that the surgical manipulation is as dainty as that on the eye, and, as a consequence, is as esthetically admired, but the collodion seal, as a sure antiseptic application, robs the subsequent treatment of its chief difficulty and danger. Were there not a more serious side to the consideration of the more commonly applied antiseptic dressings, by which the little patient is made an intense sufferer, this legacy of conservatism of the past would assume a most grotesque aspect. Some time since I saw one of these little martyrs of so-called modern science enveloped with swaddling clothes like a mummy, held in place by a plaster of Paris, fixed bandage, enveloping the little sufferer from the knees to the navel, and this in a children's hospital holding a first place in the greatest city of America.

A recent English writer tabulates several hundred operations on children, and ascribes a large share of his success to that which I unhesitatingly call a most cruel and injurious procedure.

All know that repair processes in young animals go on much more rapidly than elsewhere. The straining from crying is perhaps the greatest danger with which we have to contend. The happy child cries least, or not at all; and how can we hope to avoid these expressions of pain induced by such inquisitional surgery? The young adult, otherwise healthy, demands relief at our hands from a lifelong infirmity—an infirmity which debars him from athletics, from Government service, and from many of the more active and lucrative departments of life's vocations.

In all the older periods of life the hernial contents may not be safely and easily retained by external supports; in all the more grave and disabling conditions, where life's vocations are seriously limited, and pain and disability are present. There is a small class of cases in which the transposition of the abdominal contents is so extensive as not to permit a safe return into the contracted abdominal cavity, but this class is an extremely limited one and even there measures may be devised, preceding surgery, to make the operation usually a safe one.

OPERATIVE PROCEDURES.

In discussing the essentials, these should be reduced to the last analysis. Asepsis must be maintained, the *contents of the hernial sac* examined and reduced. The sac itself, if in any considerable degree pathologic and enlarged, is dissected to its base, evenly sutured, under slight tension, in the line of the axis of the canal and resected. The resilience of the peritoneum is quite sufficient to cause it to present an intra-abdominal smooth surface.

The suture best adapted for this purpose is a fine, double, continuous one, care being taken to coapt and *not to constrict* the included portions. The problem of restoration of the posterior wall of the canal is not so simple, owing in large measure to the deformed and weakened conditions found. Sir Astly Cooper, so far as I know, was the first to point out the singular increase of strength and reinforcement by Nature of the tendinous expansion of the transversalis muscle. Incorporated fibers of the muscle itself are sometimes seen to extend above the internal ring. When this condition exists the internal ring may be said to consist of a slightly ovate opening in the transverse muscle. One certainly finds Nature's strongest bulwark of the posterior wall of the canal to consist of these structures.

In a hernia that is at all pronounced, however, these are so weakened and deformed that they do not furnish *a secure reinforcement for the reconstructed internal ring and posterior wall of the canal. In order to give* additional strength, I have usually found it wise to include the posterior fibers of the conjoined tendon which *are coapted with the posterior fibers of Poupart's ligament.* In almost every instance in this way a safe, secure, *firm posterior wall of the canal and internal ring,* reformed high up on the cord posteriorly, may be constructed. It leaves, as lateral walls, the outer edge of the conjoined tendon and Poupart's ligament.

In other words, this portion of the canal, so far, has been restored in its normal relations and length. It now remains to replace the cord and to restore the divided fibers of the external oblique to reform the external wall of the canal. It may be well, at least for one of comparatively limited experience, to mark by forceps or suture the long, brilliant fibers of the external oblique at the time of division, and then there is an anatomic landmark for their reconstruction. I am in the habit of taking an extra suture through the structures which go to make up the upper border of the internal ring, since I have known a few cases of direct hernia to follow when the structures were unduly weak. This may not be necessary, but I deem it a wise precaution: a single mattress suture is usually the best means of reinforcement.

A third suture, subcuticular, also continuous and of the very finest type of material is taken through the deeper layer of the skin only; care should be observed that the needle does not penetrate the hair follicles or sweat ducts. If applied with proper care and accuracy, the edges of the skin are held in even coaptation. The collodion seal, reinforced by a few fibers of cotton, carefully applied and dried, finishes both the operation and the dressing.

If accurately and aseptically applied, easy, painless primary union will supervene.

Following these processes of repair, a strong, reconstructed inguinal canal is formed of normal obliquity. The intra-abdominal pressure is evenly borne by the reconstructed abdominal wall and hernia is no more likely to return than in the individual in whom the processes of normal development took place.

If the limits of this paper permitted, we would find a most interesting chapter of history in tracing the various modifications of this operation which have been recommended, especially during the last ten years.

Underlying these is a more or less intelligent effort at reconstruction to the normal pattern. The structures involved have been variably manipulated, even to the transplanting of the cord outside of the external oblique muscle. This latter method is, of course, not to be commended, since the structures of the cord are comparatively unprotected in their new relations and, at the best, emerge through a direct opening in the abdominal wall.

To all surgeons familiar with the practical advantages of the absorbable suture, it seems strange that any good operator can still be found using silk as a buried suture. Recently I discharged from the hospital a young, otherwise healthy, man who last December was operated on by one of Boston's chief hospital surgeons for the cure of hernia. By accident the cord was divided and, as a consequence, the testicle was removed. The hernia was cured, but he had had four subsequent operations because of stitch abscess. It became necessary to make a free dissection in order to find and to remove two deep silk ligatures, one of which was still encompassing the cord. The wound was reclosed by buried tendon sutures and the operation was followed by primary union. Instances of this sort are far too common to be considered accidental or ascribed to fault of technic other than the use of improper suture material.

Dr. Maynard of Dedham, Mass., in 1846 gave to the profession, as a surgical dressing, collodion, a discovery made incidentally to his research work in the investigation of gun cotton. The discovery has proved to be of very much greater value than was at first supposed, since its use in septic wounds, then almost invariably the rule, was detrimental rather than otherwise. An aseptic wound aseptically closed by aseptic, buried, absorbable sutures, is kept aseptic by the use of the collodion seal. Iodoform, in solution, inhibits the development of the *Streptococcus pyogenes albus* in the skin. The seal is loosened only by the proliferation of the epidermal cells and is absolutely trustworthy for a week or ten days. Such a seal may be reapplied, but an aseptic wound thus aseptically treated has in this period undergone processes of repair and is beyond the danger of subsequent infection.

The measures here recommended apply equally well to all aseptic wounds in all parts of the body, but they were first used and their values demonstrated in my early operative work for the cure of hernia.

Special Article

IMMUNITY.

CHAPTER XXIII.

PARATYPHOID FEVER.

Two Types of Organism.

In 1900 Schottmüller cultivated from the blood of *five* "typhoid" patients organisms which differ from the typhoid bacillus in that they attack dextrose with gas formation and are not *agglutinated* conspicuously by antityphoid serum. Since that time, many similar cases have been reported and two types of the paratyphoid bacillus have been recognized (Schottmüller). Group B causes first an acid reaction in milk which changes to a permanently alkaline reaction in about ten days, whereas Group A causes permament acidity. (Kayser.) They resemble the typhoid bacillus morphologically. These organisms are more closely related to the bacillus enteritidis than to the typhoid bacillus.

The term paratyphoid is justified only because of the similarity of the symptoms to those of typhoid fever.

"Paracolon" Bacilli.

Previous to the observations of Schottmüller, Widal, in 1897, had shown a "paracolon" bacillus to be the cause of a typhoid-like infection, and a similar observation was made by Gwyn in this country in 1898. These organisms are not different from those which are now called paratyphoid bacilli, and the infections resemble the recorded cases of paratyphoid fever. The term "paracolon" should no longer be applied to these organisms.

Methods of Infection.

The disease occurs sporadically or in epidemic form, and bears a close resemblance to mild typhoid-like epidemics which have been noted from time to time, and which, presumably, were caused by eating poisonous meats. One such epidemic of 600 cases was caused in Switzerland in 1878 by the meat of a sick calf; the *mortality* was 1 per cent. *A still older epidemic (1839)* is cited, likewise caused by meat. In both instances, the infection eventually was carried *from person to person* by contact. A recent epidemic in Kiel, proved to be paratyphoid, is assumed by Fischer to have been caused by infected *meat*, on account of the peculiar distribution of the cases *among the patrons of* a particular market. Kurth also attributed a small epidemic to either uncooked meat or milk. Fischer mentions *an epidemic* of 50 cases in East Holstein which probably was caused by the milk of two infected cows. Shortly after the epidemic began the cows died and paratyphoid bacilli were cultivated from the muscles, spleen, liver and intestines. Infected water also may cause epidemics. De Feyfer in an epidemic of 14 persons in Holland, considered that the disease was transmitted through the water of *a stream* in which the clothing of the first patients had been washed. In another instance, a regimental infection *(Saarbrücken) was traced to* the discharges of a single soldier, the water supply having become contaminated through a defective water *closet*.

Characteristics of the Disease.

Paratyphoid, like typhoid fever, is accompanied by *an* enlarged spleen and many rose spots. Although severe symptoms may be present for a time the course *of the disease* usually is mild and the *mortality* is low. The incubation period approx*imates that* of typhoid. In the few cases *which have come* to autopsy the intestinal lesions have varied from a mild ileocolitis with an intact mucous surface to a condition of superficial *ulceration*. The involvement of Peyer's patches and the *solitary* follicles which is so characteristic of typhoid is *absent, although* these structures may be moderately swollen. The *mesenteric* lymph glands are *not markedly involved* and *there is little proliferation of the* lymphoid or endothelial cells (Wells and Scott). *The* disease has no specific anatomic lesion.

Occurrence of Bacillus in the Body.

The organisms are found in the blood and various organs, in *the rose spots*, urine and feces of the patients. Practically *nothing* is known of the occurrence of the bacilli *outside the body*. Because of their presence in the stools and urine of the patients, the *methods of dissemination* and *infection* doubtless are similar to those concerned in typhoid. The *bacillus is said* to have a marked resistance to heat, withstanding 60 degrees C. for 30 minutes and *not all cells* being killed during one hour at this temperature. This *may explain the fact* that the virus is not always killed by cooking the meat. The organism probably has a wide *distribution* because of the occurrence of the infection in various *parts of the* world.

The toxicity *of the bacilli* depends on the existence of a fixed endotoxin; a soluble *toxin* is not produced.

The principles of *prophylaxis* against typhoid also *apply* to paratyphoid fever, [illegible] n that in the latter disease the possibility [illegible] n must be kept in *mind*.

The serums of patients and immunized animals acquire bactericidal and agglutinating powers for the organism.

There is no serum therapy for the infection, nor has the occasion arisen to attempt vaccination.

Agglutination and Blood Cultures.

Serum from a paratyphoid patient may agglutinate the homologous bacillus in a dilution of 1/1000 or 1/2000 or more (E. H. Ruediger), whereas the typhoid bacillus is agglutinated only in low dilutions by the same serum. However, bacillus A and bacillus B are not identical in their agglutinable properties; in this respect it is stated that the latter is more closely related to the typhoid bacillus than the former. The agglutination test is said to have a higher diagnostic value than the Gruber-Widal reaction in typhoid, a stronger agglutinating power being developed in the serum of the patient. Nevertheless, the formation of coagglutinins may render the test confusing if proper serum dilution is not practiced. Conclusions should not be attempted until the test has been performed with both strains of the paratyphoid bacillus and with the typhoid bacillus. As in typhoid, early diagnosis may be best accomplished by bacteriologic examination of the blood.

DYSENTERY (BACILLARY).

Amebic Dysentery.

In 1878, Lösch, in St. Petersburg, discovered in the stools of dysenteric patients a protozoon ameboid organism which is now recognized as the cause of amebic dysentery. The organism is called Amœba coli (Lösch) or Amœba dysenteriæ (Councilman and Lafleur). The disease prevails especially in tropical and subtropical climates, but also occurs in sporadic form or in small epidemics in temperate latitudes, and often becomes chronic.

Bacillary Dysentery.

There is another type of dysentery, an acute infection which often appears in widespread epidemic form in both tropical and temperate climates, and prevails especially in the summer months. Such epidemics occur extensively in Japan, where the mortality may be 24 per cent.; in the Philippines, United States, Germany and other European countries. In industrial settlements in Germany the mortality is about 10 per cent. (Kruse). The incubation period may be as short as two or three days. In mild cases the patient may recover in from four to eight days, whereas severe cases last from two to four weeks, during which time death may occur. Occasionally the infection lasts sufficiently long to be considered chronic.

Two Types of Bacilli.

In 1898, Shiga, basing his conclusions on positive results with the agglutination test and on the constant presence of the organism in the stools of the infected, identified as the cause of the disease in Japan a microbe which is known as Bacillus dysenteriæ (Shiga). Flexner, in 1900, made similar observations on epidemic dysentery in Manila, and his organisms or one of them, differing slightly from that of Shiga is called Bacillus dysenteriæ (Flexner), or the Flexner-Harris bacillus, Harris being the name of the patient from whom this typical strain was cultivated. Kruse (1901) found both the Shiga and Flexner types in Germany, needlessly giving the names of "pseudodysentery" bacilli to the latter. In this country similar organisms have been found as the cause of institutional dysentery by Vedder and Duval,

Summer Diarrheas.

of summer diarrheas of infants by Duval and Bassett, and by Wolstein. It is the belief of Vedder and Duval that acute dysentery, the world over, "whether sporadic, institutional or epidemic, is caused by the dysentery bacillus." We must note, however, that the organism is not found in all cases of clinical dysentery, even by skilled bacteriologists. "Clinically, 24 of our 97 cases in which dysentery bacilli were found did not differ from the cases of ileocolitis in which the dysentery bacilli were not found." (Weaver and others.) It seems certain, nevertheless, that Bacillus dysenteriæ is the most important cause of acute dysentery. It rarely occurs in the stools of healthy individuals.

Characteristics of the Bacilli.

The organism has about the dimensions of the typhoid bacillus, but is thicker. It probably is non-motile, although Vedder and Duval, in opposition to others (Lentz) claim to have demonstrated flagallæ. It often shows a polymorphous appearance in cultures, but forms no spores. It is Gram-negative. It lives for from 12 to 17 days when dried (Pfuhl); direct sunlight kills it in 30 minutes, 1 per cent. carbolic acid in 30 minutes, 5 per cent. carbolic acid plus corrosive sublimate (1/20000) almost instantaneously. It is thought that it may live over winter and cause fresh outbreaks in the spring (Kruse). The organisms of Shiga and Flexner differ in their actions on sugars (i. e., in their acid-forming powers) and in the agglutinability. "The 'Shiga' type attacks glucose, but none of the other sugars, including mannite and lactose. The 'Flexner' type attacks glucose and mannite and dextrin but not lactose." (Flexner.) The "Flexner type then is the stronger acid-forming. An artificially produced immune serum which is specific for one organism has rather higher agglutinating and bactericidal powers for the corresponding type, but low for the other. Several other organisms have been cultivated from dysenteric patients, but their variations from these two types are slight. All are certainly very closely related. In this country the "Flexner" bacillus is much more common than that of "Shiga," but here and abroad both types are met, and sometimes in the same individual.

Distribution in the Body.

In the living, the bacillus is found only in the stools of the infected, in the mucous or muco-hemorrhagic portions of which it exists almost in pure culture, few colon bacilli being in the immediate vicinity; it has not been found in the blood or urine. In fatal cases, Shiga found it only in the intestinal ulcers and swollen lymphoid structures and in the mesenteric lymph glands. Flexner mentions its occurrence in the liver. The organism, if it reaches the circulation at all, either does so in small quantities, or is rapidly destroyed by the blood. The infection resembles cholera, but differs from typhoid and paratyphoid in this respect. An observation by Markwald (cited by Lentz) indicates, however, that the bacilli may reach the circulation. A woman sick with dysentery gave birth to a child, which died within a few hours. Dysenteric changes were found in the intestines, and the bacillus of dysentery was cultivated from the diphtheritic deposits on the intestines, from the meconium and from the heart's blood. The organisms must have reached the child through the placenta from the circulation of the mother.

Lesions.

The intestinal lesions vary from a simple inflammatory hyperemia to rather extensive superficial necrosis (diphtheritic inflammation), which rarely extends below the submucosa. Such foci are said to be the most marked in the descending colon and sigmoid where mechanical injury is most likely to occur. The necrotic areas separate by sloughing, leaving superficial ulcers. The lymphoid follicles are swollen and infiltrated with polymorphonuclear leucocytes, which also accumulate in the dilated lymph spaces of the intestinal wall. The ileum is so commonly involved that the condition is called an ileocolitis. Conspicuous changes are not found in the mesenteric glands or spleen. The liver and kidneys commonly show parenchymatous degenerations.

Toxicity of Organisms.

The dysentery bacillus is a highly toxic organism. Subcutaneous injections of killed cultures in man produce a more profound reaction than the organism of either cholera or typhoid. Ordinary laboratory animals are so susceptible that they are immunized with difficulty; the horse is less susceptible. The toxicity of the organism apparently depends on an intracellular toxin (an endotoxin) rather than on a soluble toxin. When living or killed cultures are submitted to autodigestion in salt solution (Conradi, Nisser and Shiga), or when bouillon cultures are allowed to grow for 30 days, the liquids are found to be toxic after the organisms are removed. In both instances, this toxicity probably depends on the liberation of endotoxins. The question as to whether the bacillus in the intestines produces a soluble toxin which is absorbed by the lymphatics, is undetermined. It seems more probable that the conditions are analogous to those of cholera, intoxication resulting from the liberation of endotoxins by the solvent action of the tissue fluids or cells on the bacilli. Dysenteric symptoms are not produced in animals by feeding the organisms.

Dissemination and Infection.

The stools of the patient are the only known source of the organism and it continues to be excreted during convalescence. Latent or chronic cases are a source of danger to a community. Although the conditions outside the body are not favorable for the growth of the organism, it may remain living and virulent for several months. The methods of infection appear identical with those seen in typhoid. Water infection seems certain, and indirect transmission is readily accomplished by contact with the discharges. The best examples of contact infection are found in institutions, as insane asylums, or foundlings' homes, where the disease may become endemic.

Prophylaxis and Susceptibility.

The first essential for prophylaxis is correct diagnosis, for which the agglutination tests and bacteriologic examination of the stools are essential. Disinfection and other precautions should be practiced as rigidly as in typhoid. The patient should not be discharged until the stools are free from dysentery bacilli.

Poorly nourished individuals are particularily susceptible to infection, and among them the mortality is high. The disease is most common among young children, old people, and those who are confined in institutions. The conditions in Japan, however, where from June to December of one year nearly 90,000 were attacked, and in Germany, where severe epidemics occur in industrial communities, indicate that susceptibility is quite general. Digestive disturbances and enteritis from other causes are said to be predisposing factors. The normal serums of man and animals have very little bactericidal power for dysentery bacilli.

Immunity.

The subject of acquired immunity to dysentery is hardly on a satisfactory basis. The serum of convalescents shows a distinct bactericidal power for the organism, and there is good reason to believe that the acquired immunity persists for some time after the disappearance of the bactericidal amboceptors, an event which takes place rather early. As in typhoid, animals which through immunization have once been stimulated to produce antibodies, form them much more readily on the occasion of a subsequent inoculation. This acquired facility of producing antibodies may be a factor in acquired immunity. By immunizing horses, serums of rather high prootective power have been obtained. Kruse prepared a serum of which 1/80000 gram would save a guinea-pig from a dose of the bacilli which killed a control in 20 hours. It is assumed that the protective power of this serum is due to its bactericidal action. The antitoxic serum which Rosenthal prepared, by immunizing with 30 days' old bouillon cultures, protected not only against the toxin, but also against the bacilli; and conversely an antibacterial serum protected against the toxin (cited by Lentz). Such results leave us very much in doubt as to the existence of a true antitoxic serum.

Vaccination and Serum Therapy.

The value and feasibility of protective inoculations are not well established. Shiga at one time practiced mixed active and passive immunization (bacilli plus immune serum) on 10,000 individuals. This did not decrease the number of infections, although a lower mortality resulted. Shiga claims that the therapeutic use of his serum reduces the mortality to one-third of the untreated. The serum of Kruse, and also that of Rosenthal, are said to be curative; the discharges rapidly decrease in number and the course of the disease is shortened. In the hands of the Rockefeller Institute antidysentery serum proved of no distinct value.

Agglutination.

The agglutination reaction with the serum of patients shows great variability. It is sometimes absent in spite of the presence of bacilli in the stools, and often disappears rapidly during convalescence (in two weeks occasionally). It is rarely as high as in typhoid, and this is true also of artificially prepared serums. In infantile diarrrheas it commonly appears at about the end of the first week of illness (Duval and Bassett). Evidently mild cases in which the course of the disease is from four to eight days may not be recognized by means of the agglutination reaction before the period of convalescence. In chronic cases it may persist from three to four months. In a series of cases studied by Duval and Bassett, the reaction with the serums of the patients was obtained in dilutions varying from 1/16 to 1/25, twenty times; 1/40 to 1/60, twelve times; 1/100, twice; 1/200, three times 1/500, once; 1/1000 twice. No reaction was obtained with the typhoid bacillus. Kruse considers the reaction diagnostic when it occurs in a dilution of 1/50; Pfuhl, 1/30. Strong co-agglutinins for other organisms, i. e., above 1/50,, have not been observed (Lentz). The tests should always be performed with both the "Shiga" and "Flexner" types, as the two have not identical agglutinable properties, and either organism may be the cause in a given instance. The absence of the reaction does not exclude dysenteric infection positively. Bacteriologic examination of the stools is important, often necessary, for early diagnosis.

Clinical Report

A CASE OF AINHUM.

MARCUS F. WHEATLAND, M.D.

NEWPORT, R. I.

Seeing the article on ainhum by Dr. Brayton in The Journal, July 8, 1905, reminded me of a similar case which came under my care about six years ago and which was reported to the Newport Medical Society during the past year.

Previous and Family History.—M. R., negro, widow, aged 53, was born in Queen Anne County, Maryland. Her mother died in childbirth, aged 42; her father was part Indian, and died of rheumatism, aged 92; he lost both toes when about 23 years old.

The patient consulted me in December, 1899, at which time a band had formed around the base of the little toe of the left foot, and from a fissure formed at this point there came a discharge. The toe was swollen and painful. With cleanliness it improved and remained quiescent until 1903, when it again began to swell and to cause great pain. The patient stated that one evening while in great pain the toe parted from the foot as if shot from a pistol and landed about 8 feet across the room carrying with it a piece of cloth which was wrapped around it. The disease appeared in the right foot about two years previous to its appearance in the left, but the process in the former was never very active. She thinks the process in the left foot was completed in four years.

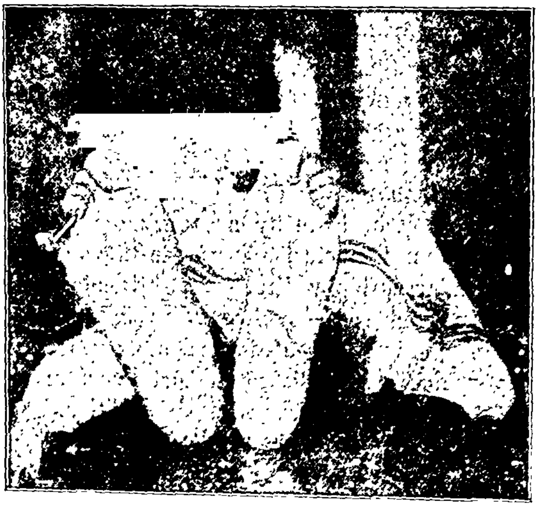

Fig. 1.—Little toe on left foot severed. Little toe on right foot constricted at base. Toe not much swollen.

RECENT ADVANCES IN PHYSIOLOGIC CHEMISTRY.

In his recent address before the American Chemical Society at its Buffalo meeting, Professor J. H. Long[1] discusses briefly some of the most important recent advances in physiologic chemistry. While the work referred to may be familiar to many, nevertheless an outline of Professor Long's address may not be without interest because it should give us a fairly definite idea of what the actual workers in this field, the physiologic chemists, themselves consider the most important lines of advance.

The first problem discussed is that of protein in nutrition, a much debated question ever since the beginning of physiologic chemistry. Liebig held that the protein substances were built up into tissues and that the oxidation of these was the sole source of muscular energy. In 1866, however, Fick and Wiolicenus showed that protein combustion was far too little to account for the muscular work done in an ascent of Faulhorn, and since then practically all who have investigated the subject have concluded that fats and carbohydrates are the usual sources of muscular energy in man. The Liebig theory implied that our protein consumption should be high, but in time the wisdom of this plan came to be doubted. If protein is of use mainly to repair waste in the tissues, why expend large amounts of extra energy on the useless metabolization of more protein many times over than necessary? Thus arose the question how much protein is really necessary for the normal body? The most conclusive answer to this question has been given recently by Professor Chittenden of Yale University, based on experiments on himself and on groups of men engaged in different occupations, the results of which are published in book form under the title of "Physiological Economy of Nutrition." These results show, as is no doubt well known to most of our readers, that the usual protein intake may be restricted greatly for persons in all ordinary occupations (professional men, soldiers, athletes), and with evident benefit so far as the general physical condition is concerned. Consequently, the Chittenden investigation marks a decided step forward in the adjustment of our diet to our physiologic needs—a most important advance in physiologic chemistry, and of direct interest to physicians.[2]

The next phase discussed by Long deals with the structure and composition of the protein molecule. This problem is even older than the previous one, and up till about five years ago the work on it was largely by way of destructive analysis, and it became established that the products of protein destruction are essentially the same so long as it is done in water. The question now arose, is it possible to build up a true protein molecule with these substances, and the answers so far obtained are connected with the two names especially, Curtius and Fischer. Curtius has produced a large number of amino groups and Fischer has synthetized a large number of substances called by him polypeptids, many of which are hydrolyzed by pancreatic juice, give the biuret reaction, etc. In this way it is expected that bodies of great physiologic interest may be constructed.

The study of the soluble ferments is another field of physiologic chemistry in which great advances are being made. A few years ago the question of digestive enzymes was looked on as settled, but the recent investigations of Pawlow has upset entirely the established conceptions of their action. Pawlow has shown that the same digestive ferments have peptic and milk-curdling powers and discovered, furthermore, a new group of ferments called kinases, or activators, the most important being enterokinase, which converts inactive pancreatic juice into active. The erepsin katabolism of peptones, described by Cohnheim, has made clearer the hitherto unknown fate of these substances, which are now believed to be split up in the intestinal wall.

Finally, Long discusses the relations of chemistry to immunity. He points out first that chemists no longer regard all theories of immunity as "visionary and intangible," and that some of the phrases of the Erlich theory are now a part of the language of organic chemistry. The controversy between Arrhenius and Ehrlich as to the character of the reactions between toxin and antitoxin, whether reversible, as claimed by Arrhenius, or not, is outlined, and the opinion expressed that at present the theories of Ehrlich and his followers, based on the presence, as they claim, of several toxins in the fibrates of broth cultures of diphtheria bacilli, may serve to advance investigation better than the Arrhenius theory, an opinion that probably coincides closely with that of immunologists in general.

We note that Long has emphasized four distinct lines along which physiologic chemistry has made and is making progress, namely, the value of protein in nutrition, the composition of the protein molecule, the soluble ferments, and the chemical relations of toxins and other substances and their antibodies. Add to the achievements outlined in these lines the fundamental rôle that chemistry is known to play in general physiologic processes and in pharmacology, and the overwhelming importance of chemistry in normal and pathologic physiology can not be denied.

---

[2] This matter was discussed very thoroughly by Dr. Billings and others in the Section on Practice of Medicine at the Portland Session of the Association.

ANTISTREPTOCOCCUS SERUM IN THE TREATMENT OF SCARLET FEVER.

Ever since the first careful bacteriologic studies of scarlet fever were made, it has been recognized that streptococci are almost constantly associated with this disease. The earlier investigations were made on the bacteriology of the throats and of the internal organs and bone marrow in fatal cases. Streptococci were found in a large percentage of these throats and organs, but the investigators regarded the invasion by these organisms as of a secondary nature and not as an essential part of the disease. More recently, blood cultures have shown that these organisms can be cultivated from the blood during life in only a small percentage of cases—12 per cent. in Hektoen's series of 100 cases. Baginsky and Sommerfeld, however, found streptococci in all the organs in every one of 82 cases which they examined postmortem. Some of these patients had died during the first days of the disease before there were signs of a secondary infection. So greatly impressed were these investigators with their findings that they have regarded the streptococcus as the etiologic factor of scarlet fever. This view has not been widely accepted, as the weight of evidence is in favor of the view that these organisms are secondary invaders.

In the light of these facts, it is not surprising that antistreptococcus serum should be tried in the treatment of this disease. This has been done by a number of investigators, among whom may be mentioned Aronson, Moser, Baginsky and Charlton. The earlier reports by these men were very encouraging, but it seems that too small a number of patients had been treated to draw conclusions from the results. Furthermore, some of these men are interested in the manufacture of the serum which they have used, and hence are probably somewhat prejudiced in favor of this treatment. Very recently Mendelsohn[1] of Baginsky's laboratory reported a long series of cases (146 in all) in which the patients were treated with Aronson's antistreptococcus serum. The mortality in this series was 9.2 per cent., which is not any better than the results obtained without serum in the mild epidemics. None of the complications were entirely prevented. Severe lymphadenitis was present in 8 per cent. of the cases and in 17 per cent. of those without serum. A larger proportion suppurated of those that were treated with serum than of those that were not injected. Otitis media developed in 13 per cent. of the injected cases and in 15 per cent. of the uninjected; hemorrhagic nephritis was present in 11.6 per cent. of the injected cases and in 12.2 per cent. of the uninjected cases.

This report shows that there is no great difference between the cases that are treated with antistreptococcus serum and those that are treated without the serum. In view of the fact that the streptococcus plays such an important part in the complications of this disease, it would seem that the failure in getting results with antistreptococcus serum must be due to improper methods of preparing the serum. We know that none of the antistreptococcus sera thus far prepared has demonstrable therapeutic value. It seems, therefore, that good results in the serum therapy of scarlet fever might be obtained if we had a more efficient antistreptococcus serum. Aronson's serum is prepared by injecting a horse with streptococcus isolated from a scarlatinal sore throat and made virulent for animals by passage through white mice. Moser's serum is said by some to have given good results. It is prepared by injecting a horse with several strains of streptococci coming from the internal organs of scarlet fever bodies. The organisms are not passed through laboratory animals before they are used in the immunization. Mendelsohn has used this serum on only four scarlet fever patients, but did not notice a marked improvement after its injection. As this series is very small, further trials with Moser's serum are indicated.

GLYCOGEN IN PATHOLOGIC CONDITIONS.

In addition to the various chemical ingredients constantly found in all animal cells, and sometimes referred to as the primary constituents, there are also secondary constituents which are not found in all cells, at least in recognizable quantities, of which perhaps the most important are fat and glycogen. Glycogen has until recently evaded successful study because it is very soluble in water, and also rapidly disappears from the cell after its death, both of which facts make it difficult to secure material in condition for examination. Methods have been devised, however, which permit of securing well-stained microscopic preparations from fresh material, and control by chemical means shows that the microscopic appearances are a reliable indication of the quantity of glycogen actually present in the tissues. During the process of evolution of these methods many and often erroneous observations and deductions have been made, which have recently undergone a clearing up at the hands of Gierke.[1] Outside of technical considerations, the glycogen question has touched on practical medicine in two chief points. The first is the diagnostic value of the occurrence of glycogen granules in the circulating leucocytes in disease; the second is the diagnostic and prognostic value of the finding of glycogen in the cells of tumors.

So far as available methods go, glycogen can not be detected in all cells under normal conditions. As is well known, it is most abundant in liver and muscle cells, after which in importance come hyalin cartilage and the middle layers of stratified epithelium. On the other hand, ordinary cylindrical epithelium, the pancreas, the nervous system, and many other organs seem quite free from visible glycogen. The usual teaching of the abundance of glycogen in fetal tissues is but partly correct; in fetal muscle it is very abundant and also in the cartilage, but during early fetal life the liver is quite free, and in other organs the amount of glycogen seems to bear no constant ratio to either the stage of development or the rate of growth.

---

[1] Deut. med. Wochft., 1905, vol. xxxi, p. 461.

[1] Ziegler's Beitr., 1905, xxxvii, 502.

This idea of a relation of glycogen to cell multiplication seems to have misled earlier observers, who suggested the existence of a correlation between the amount of glycogen in pathologic tissues and the rate of their growth. For example, Brault found glycogen in all malignant tumors irrespective of nature or origin, and, believing it to vary in amount with the energy of their growth, suggested the estimation of glycogen content as a matter of prognostic significance. The most recent studies give quite different results. Glycogen is not present in all tumors by any means, nor is it an index of their embryonal nature. It is perhaps most abundant in hypernephromas, although normal adrenal tissue is free from or poor in glycogen; in squamous celled carcinomas with hornification it is also abundant, while less so in sarcomas, and altogether absent in many cylindrical celled carcinomas. Granulation tissue cells often contain glycogen and, therefore, it may be present in tubercles and gummas, but not in a manner or quantity at all characteristic or significant.

It is impossible, on these findings, to attribute the occurrence of glycogen in pathologic cells either to an embryonic condition of the cells or to their origin, and there seems to be no specific cause for such abnormal accumulation of the substance. While the circulating leucocytes frequently contain much glycogen during suppurative processes, they may react in the same way to other injuries. Likewise, a connective tissue cell in the vicinity of an abscess, a foreign body, or a tumor, may or may not take on glycogen. Gierke has made the interesting observation that the conditions under which this glycogenic infiltration occur are almost precisely those under which fatty changes are produced, and the two processes go hand in hand. For example, in an infarcted area fatty degeneration occurs in such cells as are deprived of their blood supply but which still receive some nourishment from diffusing blood plasma—that is, the cells about the periphery. Glycogen is also found in the same cells, appearing usually before the fat, which later may entirely replace it. This fatty accumulation is attributed to lack of oxygen, with resulting lack of combustion and accumulation of fat, and Gierke considers the accumulation of glycogen to be due to exactly the same cause. Glycogen is usually found only in cells with an intact nucleus—after the cell dies the glycogen disappears rapidly, although the more stable fat may remain or may even increase. Glycogen and fat often appear in the same cell, although either may occur alone. In tumors, therefore, the cells accumulate glycogen when their nutrition becomes impaired, just as they may also accumulate fat, but this tendency is more marked in some varieties of cells than in others. Glycogen granules may be found in leucocytes either because of injuries they have received while outside the vessels in areas of inflammation or other lesions, or from the effects of poisonous substances in the blood, or, perhaps more important, from toxic injuries to the bone marrow.

From the results of the work so far performed, it may be considered that the glycogen content of tumor cells is without value as an indication of malignancy, and that glycogen accumulation within leucocytes is produced under such various conditions and in such varying amounts by similar causes as to render it of very questionable diagnostic importance.

STATISTICAL INVESTIGATION OF CANCER.

Recently there has appeared, by Drs. Bashford and Murray of England, an interesting and valuable report on the statistical investigation of cancer, published as one of the scientific reports of the Imperial Cancer Research Fund, under the direction of the Royal College of Physicians of London and the Royal College of Surgeons of England. This work represents the accumulation of a large amount of statistics and has been made possible through the collaboration of the authorities of the metropolitan hospitals, the general registrar's office, various hospitals in Ireland, the officers of the Indian and colonial medical services and also members of the veterinary profession, as well as many public and private individuals.

Through the compilation many valuable and new facts appear which will at least modify our views on some phases of the cancer question.[1] A few of these may be briefly noted:

One important indication from this study is that sarcoma increases in frequency as life advances in much the same way as that long recognized for carcinoma. This fact might suggest that the two types of growth may not be so fundamentally different as often considered. Another suggestive fact derived from a study of the age incidence in man indicates that the age period at which cancer appears in those organs in the human body which disappear early or are active throughout life presents a general parallel to the incidence of the disease in animals with short and long lives. Furthermore, the accumulated data on the frequency of cancer in animals indicate, when age is taken into account, that they are as liable to the disease as man, and that the time at which new growths appear in animals stands in direct relation to the absolute duration of life in long- and short-lived animals.

A study of the cancer question in native races has brought out certain points worthy of mention. While the data as yet are somewhat limited, still those so far collected indicate the occurrence of cancer among all the races and under all climates throughout the empire; and the report further states that there is no reason to anticipate that any race of mankind is absolutely exempt from the disease. The races include those of Malta, Fiji, British Guiana, West Indies, and others remote from civilization. The further interesting fact is brought out that diet exerts no influence on the occurrence of new growths, for just as they are found in both herbivorous and carnivorous animals so they are found likewise in those races whose diet is restricted to either vegetable or animal food, as well as to those that subsist on a mixed diet.

---

[1] They use the term cancer to include all forms of malignant new growths.

Attention is called to the importance of exercising caution in the interpretation of statistics from localities without taking into consideration the age incidence of cancer. In this way the existence of endemic centers have been thought to occur simply because the total number of individuals and their average age has not been taken into consideration.

Statistical studies of this sort, while not intended, of course, as a means of determining the nature or origin of cancer, are, however, of inestimable value in controling the conclusions derived in other ways, and they may also serve to indicate new and more favorable points of attack.

THE YELLOW FEVER EPIDEMIC.

New cases in New Orleans are not being quite so rapidly reported, and the mortality rate is steadily falling. Despite its noisy quarantine, Mississippi has some cases that have been concealed since July 20. Harsh quarantine regulations are causing widespread misery, while some enlightened communities have stamped out fever without restricting travel. It has been suggested, wrongly it is hoped, that most of the shotgun quarantines will come down when local merchants have disposed of their stocks at famine prices. If these quarantines are, indeed, mercenary in motive rather than due to cowardice and ignorance of rational methods of preventing disease, they mark one of the lowest depths of human depravity. On the Louisiana plantations the disease is finding ideal conditions for rapid spread, and the authorities find therein some of their greatest difficulties. Despite a few shortcomings, the campaign in the city of New Orleans is being valiantly fought and with real success, which will soon begin to show more graphically in the statistics. Over 40 officers of the United States Public Health and Marine-Hospital Service are now on duty in the infected area, and two have contracted the disease. While the Southern rail gateway into Illinois is being closely guarded, a few cases have developed in northern Missouri near the Iowa line and just across the Mississippi from Illinois. If the disease once obtained foothold in southern Illinois, it probably would be difficult to eradicate, if the stegomyia exists there in sufficient number, as the conditions are very difficult for effective sanitary work. The latest news from the scene of the epidemic continues to be encouraging. For instance, in New Orleans the cases that have occurred in the best quarter of the city, that above Canal street, have been mild and so far have not given rise to secondary cases. In other words, among the better classes the disease does not spread when the cases are properly cared for. Unquestionably the epidemic is checked, but continued hard work for three or four weeks yet will be necessary to show whether it can really be stamped out before frost kills the infection-bearing mosquitoes. While physicians hope for this, it will be highly satisfactory if modern methods do no more than cause the number of cases steadily to dwindle.

ETHICS IN THE COUNTY SOCIETY.

The peccadillos of a member of a county society, especially in the smaller communities, are pretty sure to be known to the other members. Very often the offending one in the little matters of professional conduct is guilty by reason of defective training and faulty early environment. Many an offender will cease his disturbing practice if the facts in their true light are kindly and tactfully laid before him. In other words, it should be the function of the county medical society to educate its members in professional conduct, and to avoid, so far as possible, trials and penalties. Rarely is there a society not numbering on its rolls at least one member capable of successfully playing the part of reformer and peacemaker. To him should be allotted the task of censor. Many an offender against professional courtesies and customs will agree to observe all the proprieties if he be properly approached. To begin an effort at reform by bringing charges against the culprit and hailing him before a trial committee does not offer the least hope of making him a better man. For instance, through ignorance or thoughtlessly, a physician occasionally permits himself to advertise in a way that offends his fellows. To win such a man over to the cause of clean medicine, charges and a trial are wholly ineffective, while in a majority of such instances private and kindly moral suasion will accomplish that end by making such a one desire to stand clean among his fellows. To this end organization in itself is a great first step. The society germinates and fosters a sense of professional pride. These things are not simply desiderata of the future. In many places they are long-established facts. Here and there over the country well-organized county societies have been blessed with members who love peace and who are willing to expend effort to rescue a misguided colleague. These men have not been so few as might be thought from the little we hear of them. Let us do away with unnecessary criticism of each others acts and have more peace conferences and fewer battles.

THE ELIMINATION OF THE MOSQUITO.

On page 585 of this issue of The Journal, Dr. Doty discusses the possibility of getting rid of that almost universal nuisance, the mosquito. It is only of late years that the habits of the insect have been carefully studied with a view to its extirpation, and yet there is much room for further knowledge which Doty points out will probably be gained by investigations now in progress. We know enough, however, to relieve ourselves, to a large extent, of the danger and discomfort caused by these pestiferous insects. The success of mosquito-killing methods in Havana and in some places along our Atlantic coast is a very encouraging indication of what is possible with well-directed systematic effort. If we had been more observing in years past, we should probably have seen the connection between the decrease of malaria and of mosquitoes in many sections of our country. It is a well-known fact that, with cultivation and drainage, malaria disappeared in extensive regions of the Middle West, but the coincident disappearance of the mosquito to any extent whatever was overlooked. Whether it will ever be possible completely to eliminate the danger from the mosquito in tropical regions with heavy rainfall is, perhaps, doubtful. We may have to rely largely on the quinin saturation method of Koch in many localities, but a great deal can undoubtedly be done. The fact that the mosquito is so much a home dweller, seldom going far from its place of origin, is a very important one, but its conveyance by steamers, railroad trains and other methods of rapid transit makes any disease of which it is the host more and more a world peril. The opening of the Panama canal may be, as some fear, the cause of the introduction of yellow fever into the Orient, and it is to be hoped that by the time that work is achieved the mosquito question will be more a matter of human control than it is at the present time. The stegomyia is apparently a cosmopolitan resident within certain degrees of latitude, a fact which involves very unfortunate possibilities if we fail to obtain a more perfect control of its migrations than we seem to have at present. The situation, however, is far more encouraging than it was as regards the possible propagation of yellow fever, notwithstanding recent developments. We have probably not yet learned all the iniquities of the mosquito, and it would be well if a still more general campaign of popular education were carried on against it.

UNCINARIASIS IN CALIFORNIA.

Dr Blumer's address on tropical diseases at the Portland session of the Association has apparently received a rather striking illustration from conditions existing in San Francisco. It is stated by the San Francisco *News Letter* that out of 115 Porto Ricans examined in that city recently, over 60 per cent. were found to be suffering from uncinariasis, and it is probable that this apparently represents the condition of the hundreds not examined. The infection seems to be fairly introduced and while it is not probable that the evil prognostications of the newspaper will be fully realized, the matter is one that deserves some public attention. The climate of California is not unfavorable to the spread of the disease and while it is not common in cities, if it should extend among the truck gardeners near San Francisco, there may be possibilities of evil to be considered.

UNWISE AND UNTIMELY EXPERIMENTATION.

It has almost invariably occurred in the history of epidemic diseases that "sure cures" are suggested, sometimes with considerable vehemence, by individuals of more or less scientific attainment, which do not stand the test of scientific investigation or experience. The present yellow-fever situation in New Orleans has been no exception to this rule, and the newspapers of the last few days have been full of notices of the prophylactic arsenic treatment of yellow fever advocated by Dr. R. B. Leach of St. Paul, Minn. According to the newspapers, he claims that the ingestion of one grain of arsenious acid in 1-100 grain doses, or continued until the epidemic ends, will render the individual immune from yellow fever. Incidentally, it is reported that thousands of boxes of arsenious acid tablets have already been sold to citizens of New Orleans. The employment of arsenic is not new. In the form of cacodylic acid (dimethylarsinic acid), as mentioned in The Journal, Aug. 17, 1901, arsenic acts "by stimulating the reproduction of cells, increasing the number of red blood corpuscles, rejuvenating the tissues and conferring on the economy an extraordinary degree of resistance to morbid influences." Dr. Leach claims that he is cognizant of from 16,000 to 20,000 tests of arsenization in yellow fever, but that these tests were made before the stegomyia had been taken into consideration. The well-known alterative properties of arsenic led to its use in yellow-fever epidemics in Brazil five years ago, and a monograph on the subject was written by Dr. Eduardo Magalhaes, a member of the Brazilian Yellow-fever Commission. If Dr. Leach's claims are valid, why were not reports made through accredited medical channels, and why has he delayed until now, in the midst of an epidemic, to give forth to the world the results of his experience and experiments? Under the conditions which at present prevail in New Orleans, the promulgation of any theory of this kind, not based on scientific principles, is dangerous to those who follow it and to others, because those who have implicit faith in the theory will not pay the proper attention to the cleaning of their premises, to the screening of their cisterns, to the oiling of places where mosquitoes might breed, and to other prophylactic measures. While Dr. Leach undoubtedly is single-minded in his advocacy of arsenic as a prophylactic of yellow fever, and while he is undoubtedly honest in his offer to submit himself and others to the test of inoculation after arsenization, he is gravely in error in making the claims he does for a procedure which is nothing more than empiric, and the following out of which, to the exclusion of approved hygienic measures, must entail grave danger to the community at large.

THE ANNUAL RAILROAD HOLOCAUST.

While few of the vast number of persons carried on American railroads suffer death or injury, the actual casualty figures are appalling. Undoubtedly the accidents of travel in America are excessive. Comparison with the casualty statistics of British railroads has so often been made that there is no need to reproduce the figures, but they are decidedly unfavorable to the railways of the United States, even though the British roads are more crowded and pass through more closely built up territory. Speed is not a factor, as there is no preponderance of accidents to the faster trains and as Great Britain has proportionally more fast trains than the United States. The annual report of the Interstate Commerce Commission for 1904, issued Aug. 16, 1905, presents the following alarming figures, to which are added for comparison those of the previous year:

	1903.	1904.	Increase per cent.
Passengers carried	694,891,535	715,419,682	3
Number of employes........	1,312,537	1,296,121	—1¼
Deaths	3,554	10,046	183
Non-fatal injuries.........	45,977	84,155	83
Passengers killed	321	441	37
Passengers injured	6,973	9,111	31
Employes killed	3,233	9,605	197
Employes injured..........	39,004	75,044	92
Passengers killed, 1904, to passengers carried as 1 to			1,622,267
Passengers injured, 1904, to passengers carried as 1 to			78,523

The statistics for years prior to 1903 exhibit, on the whole, a steady increase in tragedy. The figures are presented for information and for study. It is not in the province of medical men to ascertain the cause of this disgrace of American railroading nor to prescribe a remedy. Those functions are left to railroad men and lawmakers, with the assurance that there is herein plenty of work for both. The report shows that the installation of life-saving devices, such as automatic couplers, automatic signals, air brakes and safety switching devices, has progressed satisfactorily. Why, then, 37 per cent. increase in passengers killed and 197 per cent. in employes killed? The pages of railway journals will be scanned eagerly for a satisfactory reply. Are British railway employes of a higher grade? Are the railways of the United States not enforcing the rules that most of them have against intemperance among employes? Are dividends on watered stock given preference over expenditures for rigid and genuine "block system," elevated ways in cities and ample switching facilities? We can only ask questions. Physicians know, however, that a certain proportion of all sorts of accidents are due to the sudden onset of peculiar morbid mental states in those entrusted with hazards. This subject, in the light of the statistics here presented, demands a close and scientific investigation. Much useful effort is constantly applied to the mechanical problems of railroading, and improvements in this direction seem fully abreast of the times; but there is a most lamentable lack of any satisfactory study of the employes, i. e., of the psychology of railroading.

SMOG.

At a recent health congress in London, a member used a new term to indicate a frequent London condition, the black fog, which is not unknown in other large cities and which has been the cause of a great deal of bad language in the past. The word thus coined is a contraction of smoke fog "smog"—and its introduction was received with applause as being eminently expressive and appropriate. It is not exactly a pretty word, but it fits very well the thing it represents, and it has only to become known to be popular. London is undoubtedly the proper place for its coinage, for it is said to surpass all other places in the opacity of its smog, but so far as mere darkness is concerned some other British and American cities would afford ample justification for the use of the term.

THE PERILS OF THE LUNG TESTER.

In all our large cities there are many slot machines which, while morally innocent, have serious sanitary drawbacks. We refer to the lung testing apparatus that are found in places of amusement, saloons, etc. From a sanitary point of view there are few such appliances that are more objectionable and it is not necessary to specify why such is the case. We have not heard, however, of any general crusade against their use excepting in the city of Montreal where, though suppressed by the health authorities some years since, they have again crept in and become an insanitary nuisance calling for renewed action by the board of health. While it may seem desirable to some occasionally to test their lung capacity on these public machines, a little of the enlightenment that is going round in regard to tuberculous and other infections might be more properly applied to them than to public telephones and other comparatively innocent, but possibly or remotely dangerous apparatus.

Medical News

ALABAMA.

Hospital Reopened.—The City Hospital, Huntsville, which has been closed several months for repairs, was reopened August 15.

Hospital Company Organized.—The Union Street Private Hospital Company of Selma was organized August 9, with a capital stock of $10,000 and the following officers: Dr. Samuel G. Gay, president; Dr. John N. Furness, secretary, and Dr. Barney B. Rogan, treasurer.

Fined for Illegal Practice.—Dr. Thomas P. W. Brooks, Hackleburg, professing to be a graduate of the Georgia College of Eclectic Medicine and Surgery, was found guilty of practicing without a license, fined $25 and costs, and prohibited from practicing until he obtained a license.

Hospital Staff Elected.—The following visiting staff has been selected for St. Margaret's Hospital, Montgomery: Gynecology—Drs. Robert N. Pitts, Arthur H. Montgomery, G. J. Griel and J. H. Blue; surgery—Dr. Robert Goldthwaite, J. Norment Baker, William H. Hudson and Samuel A. Billing; medicine—Drs. Joseph L. Gaston, Milton L. Wood, John M. Sadler and Wooten W. Wilkerson; eye and ear—Drs. Paul S. Mertens, Charles A. Thigpen, William G. Thigpen, George A. Dennis and Henry S. Persons; pediatry—Drs. Charles T. Pollard, Forney C. Stevenson, Milton B. Kirkpatrick and Frank H. McConnico; genitourinary—Drs. Gibson Reynolds, Louis D. Robinson and H. T. Lay; pathology—Dr. Thomas C. Thorington, and advisory board—Drs. Charles A. Thigpen, chairman; J. Norment Baker, secretary; Joseph L. Gaston, Wooten M. Wilkerson and Robert Goldthwaite.

Personal.—Dr. Joseph D. Heacock, Birmingham, has been appointed a member of the health board of the Jefferson County Medical Society.——Dr. William W. Harper, Selma, is ill with typhoid fever.——Dr. William D. Pettus, Republic, who has been seriously ill for two months, is improving.——Dr. Wilbur F. Sadler, Montgomery, in a "personal difficulty" August 6, cut W. R. Barrett in the left temple. The wounds "are not regarded as at all fatal."—Dr. R. C. Woodson, Birmingham, has returned from Europe.——Dr. Wallace R. Bishop, Talladega, has been elected a member of the board of censors of the Talladega County Medical Society, vice Dr. T. Caffrey, removed to Dallas County.——Dr. Samuel H. Lowry, Huntsville, was stricken with paralysis July 6.——Dr. John D. S. Davis, Birmingham, has had conferred on him the degree of LL.D. by the Southwestern University, Jackson, Tenn.

ARKANSAS.

Van Leer Acquitted on Technicality.—Dr. Samuel C. Van Leer, Hot Springs, who has been under the ban of the Federal Medical Board and in trouble with the United States courts, because he prescribed hot-water baths not in accord with the regulations of the reservation, was acquitted on a technicality of procedure, August 7.

The State Board.—Drs. John W. Meek, Camden; William Crutcher, Pine Bluff, and Oscar E. Jones, Newport, are the newly appointed members of the State Board of Medical Examiners. The board reorganized July 11 and elected the following officers: President, Dr. M. L. Norwood, Lockesburg; vice-president, Dr. George V. Poyner, Green Forest; secretary, Dr. Joseph P. Runyan (re-elected), and treasurer, Dr. Ben L. Harrison, Jonesboro.

The "Drumming" Evil.—A plan is being devised by which a warning circular as to doctors' drummers may be distributed on all incoming trains by an officer under the direction of the mayor of Hot Springs. The Business Men's League is taking up the matter with the city authorities, with a view of determining the advisability of such steps.——On August 3 Alva Moore was arrested on two complaints of drumming for the Helena flats.——T. W. Standford, who was arrested on July 7, charged with a similar offense, was acquitted.

CALIFORNIA.

Manson Gives Lane Lectures.—Sir Patrick Manson, commenced the course of nine Lane lectures at Cooper Medical College, San Francisco, August 14.

Rapid Work on Hospital.—Two of the six buildings which are to make up the Merritt Hospital, Oakland, will be ready within three months. One of these is an operating pavilion, and the other a ward building three stories high.

Personal.—Dr. Stanley P. Black has been elected secretary of the Pasadena Board of Health and health officer.——Dr. Ruth A. French, Petaluma, was kicked by a horse, August 2, and sustained a fracture of the skull.——Drs. Francis M. Pottinger, Los Angeles, and George H. Evans, San Francisco, have been appointed delegates to the International Tuberculosis Congress.

Soon Loses License.—Dr. James V. Calhoun, San Francisco, recently graduated from Cooper Medical College, had his license cancelled by the State Board of Medical Examiners, August 2. It was alleged that Dr. Calhoun had advertised by means of a printed card as a private specialist, offering consultation and examination free. It was also alleged that his card contained a "grossly improbable statement."

Joint Sanitarium for Consumptives.—County Physician C. E. Stone, Marysville, proposes that steps be taken to unite with other counties of northern California and establish a joint sanatorium for indigent patients afflicted with consumption. His idea is to have the counties divide the cost of maintaining the institution, and that each send to it such patients as would otherwise be kept in separate county hospitals. By the present system such patients can not be isolated, and are allowed to mingle freely with other patients, some of whom are confined to the hospital only temporarily.

License Trials.—Dr. Walter E. Lilley, Merced, charged with practicing without a city license, was discharged August 10. ——Rudolph H. Garber, San Francisco, was arrested August 12, charged with practicing medicine without a license.——Dr. F. P. N. Van Handghen, Watsonville, was arrested for illegal practice July 18.——Fraud orders were issued July 18 against "Drs." R. Brook Sterling and R. H. Weston, San Francisco, for illegal use of the mails.——"Dr." T. J. Batiere, San Francisco, for whom a warrant was issued July 26, has fled from the city.——"Dr." S. Eve, Watsonville, under indictment for illegal practice, has left the state.——"Drs." Frank Watson and Josefa Dean of Watsonville have been arrested, charged with practicing medicine without a license.——"Dr." G. G. Sanchez, Bakersfield, is awaiting trial for alleged practice without license.——Warrants were issued for the arrest of three Chinese doctors of San Francisco, Tom She Bin, Tong Po Chy and Wong Him, on August 5.

COLORADO.

A New Sanatorium.—Dr. Henry B. Oertel has opened a sanatorium in Pueblo, thoroughly equipped for the care of obstetrical and surgical cases.

Personal.—Dr. Miller E. Preston has been appointed police surgeon of Denver, vice Dr. Francis E. Prewitt, resigned.—— Dr. Maurice Kahn, Leadville, has been appointed captain and assistant surgeon, N. G. Colo.

Correction.—Dr. William W. Bredin asks that the statement in The Journal of July 8 (page 110), be corrected. He gives the following as the facts in the case: "The city council of Denver has recently passed an ordinance to the effect that if a physician has no cases of confinement, he must send in a monthly report to that effect. I did not attend any cases of confinement during the month of May, and I failed to state that fact as many others did promptly on the first of June. . . . I was not fined . . . for not sending or reporting any birth, neither was I fined at all."

DELAWARE.

Personal.—Dr. William Marshall, Jr., has been appointed resident physician at the Delaware Hospital, Wilmington.

Unlicensed Practitioner Fined.—Charles M. Suit, Wilmington, accused of practicing medicine without a license, compromised by agreeing to refund money to persons he had been treating for cancer, and paying a fine for peddling without a license. He then left Wilmington.

Typhoid Fever in Wilmington.—An epidemic of typhoid is threatened in Wilmington, 41 cases having been reported, with, however, but few deaths. The outbreak is attributed to the pollution of the Brandywine River, from which the city receives its supply of drinking water, at West Chester and other places in Chester County, Pa.

DISTRICT OF COLUMBIA.

Personal.—Dr. William M. Sprigg has been appointed a member of the Board of Medical Examiners, vice Dr. Joseph Taber Johnson, who declined reappointment.——Dr. Frank P. Vale, police surgeon, has resigned.

Beginning of New Freedmen's Hospital.—On August 4 the first stake marking the site of the new Freedmen's Hospital, for which Congress appropriated $300,000, was driven by the superintendent, Dr. William A. Warfield.

Fined for Non-Appearance.—Drs. D. Percy Hickling and Frank P. Vale, were each fined $25 and costs for contempt of the Supreme Court of the District of Columbia, the contempt lying in their failure to appear after having been subpoenaed to testify in lunacy cases.

Typhoid in Washington.—The outbreak of typhoid fever in Washington is said to be greater in severity than any preceding epidemic, even the notable one of 1903. Since July 1 more than 300 new cases have been reported. It is stated that the new filtration beds would be ready August 19, and that after that date pure water would be supplied to the city.

ILLINOIS.

New Hospital Dedicated.—The Evangelical Lutheran Hospital at Granite City, erected at a cost of $40,000, and having accommodations for 96 patients, was formally dedicated August 13.

Princeton Hospital.—The Princeton Hospital and Sanitarium, which has been closed for a time, has been purchased by Dr. Matthew H. Blackburn and will soon be thrown open to the public.

Chooses Hospital Staff.—The board of Lakeview Hospital, Danville, met August 7 and elected the following staff for the coming year: Medical—Drs. Elmer B. Cooley, Henri S. Babcock, Abraham L. Fox, Francis W. Barton and Fred Baumgart, Danville; Dr. Jesse H. McIntosh, Vermilion Heights, and Dr. Jacob G. Fisher, Catlin. Surgical—Drs. William A. Cochran, Thomas E. Walton, A. Merrill Miller, Charles E. Wilkerson, Stephen C. Glidden and George L. Williamson, Danville; and eye and ear, Dr. Elbert E. Clark, Danville.

Chicago.

Home from Europe.—Drs. James B. Herrick and Henry Harms have returned after a summer in Europe.

Laboratory Moves.—The demolition of the county building has necessitated the transfer of the municipal laboratory to temporary quarters at Michigan Avenue and Fourteenth Street.

The Weekly Mortality.—The deaths for the week ended August 19 numbered 577, an increase of 38 over the previous week and of 140 over the corresponding week of 1904. Acute intestinal diseases caused 145 deaths; violence, 69; consumption, 46; nephritis, 35; nervous diseases, 33; heart diseases, 31, and cancer, 26. Among the important causes of death showing decreases are apoplexy and heart diseases, each 6 less; bronchitis and sunstroke, each 3 less; acute intestinal diseases, 55 less, and pneumonia, 14 less. Among those showing an increase are Bright's disease, 5; consumption, 10; cancer, 4; nervous diseases, 16; whooping cough, 4.

IOWA.

Sanitarium Opened.—Maple View Sanitarium, West Union, has been opened recently under the management of Drs. Frank B. Whitmore and Allen G. Rennison. The sanitarium has accommodations for 12 patients and is the only hospital in Fayette County.

It Costs to Be an Itinerant.—The Dubuque city council has amended the present ordinance by fixing the license for traveling doctors at $5 a day straight. If the doctor carries a band or concert company $10 a day extra will be charged for the first day and $5 for each subsequent day.

Hospital Accepts Conditions.—The Council Bluffs Woman's Christian Association has accepted the gift of $40,000 offered by J. D. Edmundson, Des Moines, under the conditions that the new hospital should be known as the Jennie Edmundson Memorial Hospital, in memory of his deceased wife; that the association provide a site and secure an additional $10,000.

KENTUCKY.

Off for Europe.—Dr. John D. Maguire, Lexington, sailed for Europe, July 22.——Dr. Stephen Sharp, Jr., Covington, sailed for Europe, August 6.

Kentucky Graduates.—On July 12 a class of 48 was graduated from the Kentucky School of Medicine. Dr. William H. Wathen delivered the announcement, and John H. Leathers conferred the degrees.——Kentucky University Medical Department graduated a class of 58, June 30. Rev. E. L. Powell delivered the doctorate address and Dr. Joseph B. Marvin conferred the degrees.——Dr. James M. Bodine delivered the faculty valedictory at the graduating exercises of the University of Louisville Medical Department, June 29, when a class of 25 received diplomas from Hon. Theodore L. Burnett.——Hospital College of Medicine, Louisville, graduated a class of 89, July 3. Addresses were made by Dr. Thomas Hunt Stucky and Dr. J. H. Blanton.

Sues State Board.—Dr. Samuel J. Fryer, Louisville, has entered suit against the State Board of Health to compel that body by mandatory injunction to issue him a certificate to practice medicine. He claims that he graduated from the Hospital College of Medicine and applied to Dr. W. H. Wathen, the county referee, for a certificate in July, 1903, and presented his diploma. He made a second application in January, which was also refused. The plaintiff claims that he graduated before the law requiring examinations went into effect, though after it was passed. For this reason he contends that he should not be subjected to the examination. Another member of the same class, it is said, recently sued the board and received his certificate.

MARYLAND.

Money for Hospital.—Toward building the proposed Union Hospital of Cecil County at Elkton, $4,500 of the $5,000 required to secure an appropriation from the state, has been obtained.

Smallpox.—The outbreak of smallpox in Calvert County is said to be limited to three cases on Fishing Creek, near Pushaw Station, on the Chesapeake Beach Railroad, who are under the care of Dr. J. L. Brayshaw, Friendship.

Fail to Report Tuberculosis.—There is much complaint by the State Board of Health that physicians fail to report cases of tuberculosis. This is pretty general throughout the state, notwithstanding the law passed at the last legislature requiring reports, and affixing a penalty of $100 fine and not exceeding six months' imprisonment, one or both, in the discretion of the court, for its violation. Publicity in such cases is forbidden. The secretary of the board declares his intention of enforcing the observance of the law.

Baltimore.

Pharmacist Dies.—Charles Schmidt, associate professor of pharmacy, University of Maryland, died August 14 from typhoid fever. He was director of the laboratories of Messrs. Sharpe & Dohme.

Personal.—Dr. Henry M. Hurd of the Johns Hopkins Hospital has gone to the Adirondacks for the remainder of August. ——Dr. William Sidney Thayer has gone to Cape Breton for the remainder of the summer.——Dr. Gordon Wilson has gone to North Hatley, Canada, for some weeks.——Dr. William M. Dabney has gone to Portland.——Dr. William M. Welch is in Paris.——Drs. James Bosley, John B. Schwatka and J. D. Norris have gone to the Antlers, I. T., where they will spend three weeks in hunting big game.——Dr. George A. Fleming is at Bar Harbor, Maine.

NEW YORK.

Attempt to Bribe Inspector.—Dr. William S. Goodale, Buffalo, tenement house inspector, accuses an owner of a tenement house with having offered him a bribe of $25 provided that he failed to report violations of the tenement house ordinance.

Improving Nassau Hospital.—This institution, located at Mineola, L. I., will be provided with a children's ward, diet kitchen, dressing room and more private rooms by Mrs. W. K. Vanderbilt, Jr. The addition will be about as large as the present building, and the ground has already been broken.

Organize Medical Library Association.—Physicians of Jamestown have organized this association to maintain a library at the W. C. A. Hospital. Dr. Era M. Scofield was elected president; Dr. Jane L. Greeley, vice-president; Dr. John W. Nelson, secretary, and Dr. John H. Wiggins, treasurer.

New York City.

Personal.—Dr. Henry Belt was thrown from his carriage in an accident at Narragansett Pier, R. I., breaking his arm and sustaining several lesser injuries.

New Tuberculosis Camp at Coney Island.—The system of treatment which is being carried on is the same as that used at Sea Breeze House. This is a summer hospital for the treatment of surgical tuberculosis, and was opened under the direction of Dr. Napier. Twelve children suffering from various forms of bone tuberculosis are now being treated in the hospital, which is a tent on the grounds of the reception hospital.

Examine Subway Air Again.—A large assortment of samples of subway air has been collected from different portions of the subway and from the basements of department stores, factories, tenements, etc., which Dr. George A. Soper, consulting sanitarian of the Board of Health, is analyzing for the purpose of ascertaining the relative conditions of the atmosphere in these various localities. Dr. Soper will make a definite report in about two weeks.

Healer Fined and Jailed.—For swindling poor folk of the East Side, posing as a physician, "healer of the sick," Alfred Meyer, a former convict, was sentenced August 4 in the Court of Special Sessions to eleven months in the penitentiary on Blackwell's Island, and to pay a fine of $500 or to serve in prison one day for each dollar not paid. There were more than 500 complaints against Meyer, of which the chief probation officer said he had personally investigated 150 and found their stories true.

Fight Over Bellevue Bids.—An application to make permanent a temporary injunction granted by Justice Amend restraining the trustees of Bellevue Hospital from awarding the contracts for pavilions A and B of their new building was heard by Justice Dowling in the Supreme Court. The action was brought by a taxpayer, who sets up the claim that the work was awarded to one who had not made the lowest bid and also because it was not made at the regular time and place of meeting of the board of trustees.

Typhoid Fever Spreading.—This disease is spreading in both Manhattan and Brooklyn. From August 12 to August 18 148 cases were reported to the Health Department. Of the new cases 27 were in the Bath Beach district. The reports from this district have not been in the least exaggerated. Policemen have been stationed at the bathing houses in the neighborhoods of the outlets of sewers, to warn people away, as it seems almost certain that some of the cases are due to bathers carelessly swallowing water in this vicinity.

Bakers' Strike and Tuberculosis.—As a result of the strike among the Kosher bakers on the East Side the Board of Health has made an investigation and issued the following statement: "While tubercle bacilli may be present on the hands of the bakers and be mixed with the dough, yet they are almost certainly killed during the process of baking. This destruction is still further insured by the bread being in the moist state. It is remarkable that among 2,400 patients applying for treatment at the tuberculosis clinic of this department from March 1, 1904, to March 1, 1905, not a single one followed the baking trade."

Many Diseased Children.—The Health Department, under the direction of Dr. Biggs, just completed an important investigation into the health of some of the school children of this city. Out of 13,941 children in four primary schools, 6,294 required medical attention for some abnormal condition. They were all in poor quarters, but the worst quarters for disease were avoided in order that the results might be taken in general. The complete result is as follows:

Bad nutrition	1,092
Swelling in anterior glands	2,604
Swelling in posterior glands	706
Chorea (nervousness)	136
Cardiac disease	232
Pulmonary disease	204
Skin disease	227
Deformity of spine	118
Deformity of chest	162
Deformity of extremities	210
Defective vision	3,219
Defective hearing	460
Nasal breathing	1,623
Bad teeth	3,314
Deformity of the palate	196
Bad mentality	823
Requiring medical attention	6,294
Total number examined	13,941

Contagious Diseases.—For the week ended August 5 there were reported to the sanitary bureau 402 cases of tuberculosis, with 141 deaths; 223 cases of measles, with 8 deaths; 193 cases of diphtheria, with 21 deaths; 122 cases of typhoid fever, with 13 deaths; 47 cases of scarlet fever, with 1 death;

24 cases of cerebrospinal meningitis, with 12 deaths; 3 cases of smallpox, with 1 death, and 17 cases of varicella.——For the week ended August 12 there were reported 421 cases of tuberculosis, with 165 deaths; 254 cases of typhoid fever, with 26 deaths; 178 cases of measles, with 9 deaths; 177 cases of diphtheria, with 25 deaths; 26 cases of cerebrospinal meningitis, with 19 deaths; 37 cases of scarlet fever, and 12 cases of varicella.

OHIO.

Cincinnati University.—At the request of the medical directors of the City Hospital the Board of Public Service adopted a resolution that hereafter the professor of pathology of the Cincinnati University shall be the head of the pathologic department of the hospital. The directors stated that they had been made convinced of the fact that a professorship of pathology would soon be added to the university staff.

Personal.—Dr. George Fisher, formerly physical director of the Cincinnati Y. M. C. A., has resigned his position of physical director of the Brooklyn Y. M. C. A. in order to become one of the general secretaries of the national committee of the association. He is spending a few weeks in Cincinnati before going to California to strengthen the organization in that state.——Dr. Eugene S. May, Cincinnati, has been appointed local surgeon for the B. & O. S. W. R. R.——Dr. W. Burnett Weaver, chief surgeon of the Cincinnati Traction Company, has resigned, and sailed for Europe, August 16.——Dr. Clyde R. McKinniss, Marion, has been appointed to the staff of the Columbus State Hospital for the Insane.——Dr. Sterling B. Taylor, Columbus, was detailed as surgeon to Troop B, during camp, from July 30 to August 6.——Dr. Frank Winders, Columbus, secretary of the Ohio State Board of Medical Examination and Registration, has tendered his resignation, to take effect Jan. 1, 1906, on account of the increased duties consequent on his election as secretary of the Ohio State Medical Society and editor of the *Ohio State Medical Journal.*

PENNSYLVANIA.

Typhoid in Allegheny.—There are at present 76 cases of typhoid fever under treatment in hospitals in Allegheny. The number of cases not in hospital is estimated by the Pittsburg *Dispatch* at 1,520. Meanwhile the superintendent of the local health board is said to deny the presence of the disease in the city.

Personal.—Dr. William N. Stein, Shenandoah, sailed for Glasgow on the *Astoria,* August 5.——Capt. Louis P. McCormick, Connellsville, has been appointed major and surgeon, N. G. Pa., and assigned to the Tenth Infantry, and Dr. James F. Elder, Beaver, has been commissioned first lieutenant and assistant surgeon in the same command.

Typhoid Fever at Dundaff.—Dr. Dixon, state health commissioner, has detailed Dr. Fred C. Johnson, chief medical officer of the State Department of Health, to make an investigation into the cause of the typhoid fever epidemic at this place, and to institute measures to prevent its spread. Dr. George Fox of Philadelphia will assist Dr. Johnson with the work.

Philadelphia.

Personal.—Dr. C. Albert Bigler, Jr., sailed for Europe on the *Etruria,* August 19.——Dr. J. Howard Taylor, assistant medical inspector in the Bureau of Health, who was rather severely injured by a fall August 16, is rapidly recovering.——Dr. Richard F. Woods was severely burned by the explosion of the gasoline tank of his automobile August 13, but is now recovering from the injury sustained.——Dr. Alfred Stengel, chief of the medical staff of the University Hospital, is confined to that institution with an acute intestinal affection. He has not typhoid fever, as was first reported.

Food Commission's Busy Month.—Since the middle of July Dr. B. F. Warren, state food commissioner, and his assistants have arrested 112 dealers in this city, charged with adulterating food products. All have had a hearing and have been returned to court for trial. The cases only covered five products, namely, 20 milk cases, 19 for alleged adulteration of chocolate cake, 2 for candy, and 9 on the charge of selling adulterated preserves and jam. So far this month there have been 19 cases of alleged adulteration of cake, 1 candy, 5 preserves and 37 on the charge of selling adulterated soft drinks.

Health Report.—The total number of deaths reported for the week aggregated 438, the same as for last week. The deaths in the corresponding week of 1904 aggregated 420. The principal causes were: Typhoid fever, 11; whooping cough, 4; cerebrospinal meningitis, 2; tuberculosis, 42; cancer, 30; diabetes, 3; apoplexy, 22; heart disease, 30; acute respiratory disease, 16; enteritis (under 2 years), 73; enteritis (over 2 years), 13; Bright's disease, 35; railroad injuries, 6; marasmus, 11. There were 185 cases of contagious diseases reported, with 14 deaths, as compared with 152 cases and 19 deaths for the preceding week. There were 125 cases of typhoid fever reported, with 11 deaths, as compared with 100 cases and 14 deaths for the previous week. It will be noted therefore, that typhoid fever is on the increase, though the malady is of a mild type and the mortality relatively low.

GENERAL.

Personal.—Dr. Joseph Ford, United States Army, who has been stationed in Oklahoma, was operated on for appendicitis at the General Hospital at the Presidio, San Francisco. As soon as he has recovered he will go to the Philippines for duty.

May Have Cure for Leprosy.—A later report is given out concerning the cure for leprosy which physicians in the Philippines are said to have discovered. The report states that 25 patients have been treated; of these 6 are reported as being absolutely cured while the others have been benefited. No official statement is received.

American Electrotherapeutic Association to Meet.—The fifteenth annual meeting of this association will be held at the New York Academy of Medicine, New York City, September 19-21. The program includes papers on all branches of electrotherapeutics, including the treatment of cancer and other malignant growths, tuberculosis, syphilis, gonorrhea, etc., by various forms of electricity, radium and its therapeutics, manual therapy, mechanical vibration, etc. Authors of papers include Drs. Rockwell, Cleaves, Massey, Granger, Baer, Snow, Reyburn, Kassabian, Stover, Gibson, Lindsay, Curtis, Roberts, Herdman and Deeks. The secretary is Dr. Clarence Edward Skinner, 67 Grove Street, New Haven, Conn. The chairman of the committee on arrangements is Dr. Morris Weil Brinkmann, 54 West Ninetieth Street, New York.

Mortality on Shipboard Among Immigrants.—Dr. E. T. Chamberlain, chief of the Bureau of Navigation of the Department of Commerce and Labor, reports that during the past three fiscal years ended June 30, 1905, from the ports of Europe 1,932,934 steerage passengers embarked for New York, of whom 423 died on the voyage, or about 22 deaths per 100,000 passengers. Allowing twelve days for the average voyage, the rate is equivalent to an annual death rate of about six and one-half (6.56) per 1,000. The highest monthly rate for the three years was January, the month of smallest travel, 38 deaths out of 87,260 in the steerage; the lowest rate, also 38 deaths, out of 256,838 steerage passengers, was May, one of the months of heaviest steerage travel to New York. Among the immigrants from northern Europe there were 242 deaths out of 1,351,221 steerage passengers; among those from southern Europe 181 deaths out of 581,713. Of the steerage passengers 31,873 were babies under one year, and 116 more were born in the steerage, two mothers dying in childbirth; 126,993 were children over 1 and under 8 years, and 1,774,068 passengers were over 8 years. Under 8 years 211 died; over 8 years, 212. The census figures for 1900 give deaths under 9 years in the United States, so exact comparison is not practicable. In the steerage one and one-third died out of every 1,000 children under 8 years. Only one steerage passenger out of nearly 2,000,000 died on shipboard from accident, and only one from yellow fever. Twenty-three committed suicide and seven disappeared (suicide, accident or murder). The principal causes of death were: Heart failure, 75 (20 children); pneumonia, 64 (37 children); inflammation of bowels, 40 (all children but five); meningitis, 34 (14 children); convulsions, 28 (children); apoplexy, 17; alcoholism, 17; marasmus or weakness, 17 (13 children); tuberculosis, 16 (8 children); bronchitis, 15 (12 children); congestion, 10; 5 children died from scarlet fever and 5 from measles. The remaining 47 deaths were due to 27 miscellaneous diseases.

THE YELLOW FEVER SITUATION.

EXTENSION OF DISEASE—RELATIVELY LOW MORTALITY—SEPTEMBER FEARED—FUMIGATION DAY IN NEW ORLEANS.

Louisiana.

Reinspection and Repair of Screens.—Flying squadrons have been organized to reinspect and repair screens in New Orleans.

Arrested for Failure to Screen.—Hart Newman was arrested August 22 for failure to screen three cisterns at Athletic Park, a resort owned by him.

Personal.—Surgeon Thomas D. Berry, United States Public Health and Marine-Hospital Service, has recovered from his attack of the fever.——Dr. John T. Crebbin, New Orleans, contracted the fever and has been gravely ill.——Surgeon Joseph H. White, United States Public Health and Marine-Hospital Service, has been made an honorary colonel on the staff of Governor Blanchard.

Resigned Rather Than Quarantine.—At Bayou Gaul the health board resigned rather than institute the quarantine demanded by citizens.

Mail Fumigation Unnecessary.—Some towns asked that New Orleans mails be fumigated, but the postmaster, after consultation with Dr. White, in charge of affairs, decided it was unnecessary.

Must Not Ship Bananas.—Surgeon-General Wyman ordered that no banana cars be shipped north from New Orleans on account of inability to destroy the mosquitoes that they are very likely to transport.

Many persons in New Orleans, including President Charles Janvier, president of the citizens' yellow fever committee, have been fined for failure to screen cisterns, etc., in accordance with the new mosquito ordinance. The courts are vigorous in sustaining the measure.

Wanted Militia to Abate Quarantine.—Local quarantines became so annoying that the State Board of Health and the governor considered calling out the militia to enforce the moderation orders of the state board.

Cases Increasing, Mortality Lessening.—There are more new foci in the good part of New Orleans and more prominent people are suffering, but the mortality is steadily less—very small among those well cared for from the beginning.——Nearly all new cases are near the originally infected area.

Fumigation Day.—On Sunday, August 20, nearly 300 tons of sulphur was burned in the effort simultaneously to destroy mosquitoes in every house in the city.——Four or five tons of wire screens are daily shipped into New Orleans.

Good Work of Committees.—The volunteer ward committees of New Orleans, under the splendid leadership of Rev. Beverly Warner, have accomplished wonders. Every room has been inspected. On one day every gutter in the city was salted to kill vegetation and mosquitoes.

Comparative Mortality.—The figures show a decreasing mortality. Comparing as of date August 20, the cases and deaths of this epidemic and that of 1878 we find:

	1878.	1905.
Cases to August 20	1,355	1,397
Deaths	496	201
Percentage mortality	37.	14.

Quarantines Recoil.—Prolonged quarantines are proving costly to the small towns, both directly and indirectly.——When a suspected case occurred at Bon Ami, the town found that absolute non-intercourse quarantines having suspended train service, it could not receive the services of a fever expert whom it asked the State Board of Health to send.——A case at Lafayette on August 1 caused a turning of the tables, as the town, after having been most rigid in its quarantine, now found itself cut off by the neighboring places.

A Second Marine-Hospital Surgeon Attacked.—Dr. Maxine Landry, United States Public Health and Marine-Hospital Service, was reported, on August 22, to be ill with the fever.

Immune Nurse Dies.—An immune nurse who went through the Cuban experience died of a second attack.

Fever Spreads in New Orleans.—The fever has spread to the St. Louis Cathedral and the Court buildings.

Freight Held Up.—Freight for the Isthmus of Panama in enormous quantities is being delayed at New Orleans by the interference with shipping.

Fever in Jail.—An Italian ill with fever spent Sunday in jail and created a panic when brought into court on Monday of this week.

Train Inspection Extended.—Surgeon Young, United States Public Health and Marine-Hospital Service, has charge of the train inspection service running out of New Orleans, and has extended the service in thorough fashion as far north as Memphis, Tenn.

Detention Camps.—On August 17 Camp Wyman had seventy-five inmates and a waiting list of 243; Camp Slidell had twenty inmates and 107 waiting, and Camp Avondale seventy-five inmates with a waiting list of 235.

Cross Purposes.—At Lake Charles the board of health wishes to admit freight from New Orleans but the citizens and municipal officials have thus far prevented such action.

Panic and Scarcity of Food.—Panic exists in the small towns and in those along the Gulf coast there is a scarcity of provisions, due to the many obstructing quarantines.

Conditions Favorable for Spread.—United States Public Health and Marine Hospital Service recognizes that the conditions are favorable for continued spread of the disease, and feels that to restrict it within reasonable limits will be a great measure of success.

Penalty for Not Reporting Cases.—A few of the older physicians even yet are unwilling to report their fever cases. To these Surgeon White has announced that prosecutions are certain and that the penalty will be, not only a fine, but imprisonment.

Banana and Oyster Famine.—Bananas are becoming scarce in New Orleans because of the embargo on fruit steamers from the tropics. The available supply is said to be coming via Mobile, and there is fear that the shipments bring with them a good many stegomyias.——New Orleans is also threatened with scarcity of oysters.

The New Orleans Record.—In New Orleans for the week ending August 12, there were 54 deaths from yellow fever in 112 from all causes, nearly half the week's mortality. Exclusive of negroes, the death rate for the week was 24.80.

The New Orleans record for August 21, 1905, is as follows:

Total cases to date	1.458
Total deaths to date	210
Percentage mortality	14.4 per cent.

Sanitary Work Should be Continued.—Surgeon White, addressing the ward presidents of the volunteer sanitary, emphasizes the necessity of making the organization permanent and continuing the work until, at least, the disease ceases. He said that once a week a "mosquito killing day" would be necessary, and that once every seven days all gutters must be flushed. The cistern inspection must continue and must be thorough. Until screening is perfect, cisterns must be oiled, and with high-grade oil to avoid unpleasant consequences.

Arsenized Devotees Die.—It is reported that 12 of the recent deaths from yellow fever have been of adherents of the arsenic theory exploited by Dr. Leach. A formal letter was issued August 22 by Surgeon J. H. White, United States Public Health and Marine-Hospital Service, and by the president and advisory committee of the New Orleans Medical Society, telling how patients were under treatment who had partaken of the arsenic diet for the supposed sufficient period to render them immune. The letter was drawn forth by the announcement that there would be a mass-meeting of the arsenic adherents Wednesday or Thursday night to denounce the medical practitioners of New Orleans.

The Arsenization Idea.—Some difficulty has arisen from the notoriety attending the visit to New Orleans of Dr. Reginald B. Leach, a homeopathic physician of St. Paul, Minn., who holds that arsenization is a preventive of yellow fever infection. He has talked freely to the newspapers and has addressed public meetings of sympathizers. He announced that he came to New Orleans to give his theory a practical demonstration, by allowing himself to be bitten by an infected stegomyia. He refused to go on with the experiment unless it was conducted by the New Orleans Medical Society, which refused his request, not caring to countenance an experiment that might result in death and not having any active members who could well be spared from the active fight against the disease. Many physicians fear an epidemic of arsenical poisoning, the popular love for a "specific" having led hundreds, after reading Dr. Leach's newspaper interviews and articles, to eat arsenic. Belief in this extraordinary theory has led many citizens of New Orleans to ignore the orders of Dr. White and his assistants. The eaters of arsenic pills have neglected to clean up their premises and screen their cisterns. Orders were issued on August 18 for the instant arrest of all who have failed to obey the mosquito ordinance. The disciples of Dr. Leach held an indignation meeting at which the medical profession and the press were jointly denounced.

Outside Parishes.—Calcasieu Parish, which stopped through traffic on the Southern Pacific, has since ameliorated its restrictions.——Madison Parish barred out freight and drugs as well as passengers. However, a case of fever developed at Tallulah, in the parish.——Rapides Parish has ameliorated its quarantine.——The conditions in St. John and St. Charles Parishes are exceedingly bad, the houses of the poor being full of mosquitoes. Dr. Corput, M.H.S., is in charge and has his hands full. Many are so anxious to get away that crowds wait their turn to undergo the ten days required at the detention camps.——Jefferson Parish had five cases, all imported from the original New Orleans focus. No quarantine was established, but the cases were promptly and effectively isolated, while a campaign was waged against mosquitoes. The disease has disappeared from the parish, though there is daily mingling of the citizens with the people of New Orleans.

Other Towns.—Gueydan condemns panic quarantines.——Washington announces that it is a clean town, that mosquitoes are exterminated and trains are forbidden to enter the town.——Mansfield admits daily an engine and a mail car.——Baton Rouge has erected a yellow fever hospital, and is busy oiling and screening.——Sporadic cases have occurred at Diamond, Sarpy and Reserve plantation.——Patterson has had a number of cases.——Many cases have been discovered at the mouth of Bayou La Fourche.——Alexandria admits mail.——Algiers, a town of 20,000 population, just across the Mississippi from New Orleans, had a case of yellow fever late in July. The patient was properly screened and mosquitoes were killed. After the lapse of three weeks a house-to-house canvass showed that the disease had not spread.——No new cases have occurred at Shreveport and quarantine is relaxed.——La Place has a number of cases.——Allentown and Pleasant Hill are isolated.——On August 17 the situation near New Orleans was as follows: Diamond plantation, St. Charles parish, twenty-six cases, three deaths; Alexandria detention camp, three cases; Patterson, St. Mary parish, fifty-two cases, one death; Tallulah, Madison parish, three cases, one death; Pointe Celeste, Plaquemines parish, seven cases, one death; Lafayette, two cases; Rayne, two; La Place, twenty-one; Terre Haute plantation, four; Bucktown, one; Willswood plantation, five cases, two deaths; Empire plantation, one; Sunrise, Plaquemines Parish, one; Bayou Cook, one case, one death.——New cases were found on August 18, at Hanson City one, at Shrewsbury two, at McDonogesville one, at Pecan Grove five, as well as six new cases at Patterson, with one death.——The one victim at Alexandria died.——Ouachita has abandoned its shotgun quarantine.——Iberville called off its quarantine but an influx of refuges from infected Bayou Goul led citizens to demand the rigid quarantine, and in consequence the health board has resigned.——On August 21 Hanson City reported eight new cases, Kenna four, Iberville two, Corinne two, and Patterson ten.——Riverside reports, to August 18, forty--eight cases and three deaths.

Funds to Fight Fever.—Governor Blanchard has arranged with bankers to furnish $100,000 as the state's contribution to the New Orleans fund to fight the epidemic.——Three New York life insurance companies—the Mutual, the New York Life and the Equitable—have each been asked for $50,000 contributions.

Interparish Conference.—Lafayette was the scene on August 8 of a conference of officials from the parishes of Calcasieu, St. Landry, Acadia, Vermillion and Lafayette, at which a schedule of uniform quarantine regulations was adopted. This permits re-establishment of through passenger travel and provides five-day detention for those from New Orleans and other infected points, responsible inspectors, uniform certificates, and permits entrance of fumigated baggage.

During two days at Leeville there were found 69 positive cases of fever, 53 suspicious cases and 145 cases of dengue. There are about 300 houses and families there and not a single house but has one or more cases of sickness. The people are distracted. All seem to have lost ambition to work. They are completely demoralized. Two more deaths are reported there.——Patterson reports 15 new cases and no deaths. St. Tammany parish reports a case on the road between Mandeville and Lewisburg. Hanson City reports 6 new cases, Kenner 1 and Sarpy plantation 2. There was one death on Elizabeth plantation in Iberville. St. Rose, in St. Charles parish, has 2 cases and 1 is dead. Corinne plantation, in St. Bernard parish, reports one death. Mississippi City reports 3 new cases.

Other States.

Alabama.—Tuscaloosa is quarantined against all yellow fever points and enforces a two-weeks detention.——The Mobile quarantine against New Orleans is to last until December, unless earlier revoked.——Dr. John Guiteras of Havana, on August 15, addressed the citizens of Mobile on the subject of yellow fever.——The Jefferson County Medical Society at Birmingham, on August 14, decided by unanimous vote to ask for the raising of the quarantine against Montgomery.

Arkansas.—Having secured a state quarantine through the aid of the militia Dr. Cantrell asked local boards to withdraw their quarantines.——Texarkana reports a quarantine death, a quarantine guard having fatally shot a citizen running over the line.

Florida.—State health officer, Dr. Joseph Y. Porter, on August 14, extended the detention period for entry into the state from six to ten days.——The Hillsboro County Medical Society meeting at Tampa was addressed by Dr. John Guiteras of Havana and Dr. Porter, state health officer.——A few cases of dengue at Tampa caused a yellow fever scare.

Georgia.—Augusta has instituted an "absolute non-intercourse quarantine" against all infected places.——Columbus requires twenty days' detention before coming within five miles of the town.——The United States Public Health and Marine-Hospital Service has opened an office in Atlanta, in charge of Dr. Charles P. Wertenbaker, for the issue of health certificates.——Cordele requires twenty-one days' absence from an infected point before granting admission.——The mayor of Savannah has asked Surgeon-General Wyman to throw a cordon of soldiers around New Orleans, allowing no one to leave the city until after having undergone five days' detention under observation.——Atlanta was much displeased with a story in the New York Tribune of August 11 alleging there were at least a dozen concealed cases of yellow fever in that city.

Illinois.—Cairo and southern Illinois is now quarantined against the states of Louisiana and Mississippi, and all fever infected points in other states, and no passengers coming from either of those states or places will be admitted to Cairo unless they can show health certificates signed by a duly authorized and accredited board of health, showing that they have not been in the above-named sections within ten days. Furthermore, the city of Cairo is quarantined against the world, and no person can come into the city from any place unless they can show health certificates showing that they have not been in a fever infected district in ten days.——It was announced from Cairo on August 13 that Dr. Egan of the Illinois Board of Health and Dr. A. T. McCormack of the Kentucky board had arranged all differences regarding certificates and travel. However, on August 21, from the same place it was announced that Illinois would not receive certificates issued at Paducah, Bowling Green, Fulton or McCracken County, Ky., or at Bird's Point, Mo. No one can get into or through Cairo now without a satisfactory certificate of health.——Many refugees from Louisiana are in Chicago, Evanston and nearby places.

Indiana.—Dr. T. Victor Keene, city sanitarian of Indianapolis, has gone to New Orleans to study yellow fever.

Kansas and Missouri have a uniform quarantine.

Kentucky.—Two detention hospitals have just been erected by the railroads entering Louisville from the south, to be used to care for persons reaching the city who are sick. Louisville has opened her doors to yellow fever refugees, and Kentucky will not quarantine. Dr. John H. Ward has been appointed an assistant to the Health Office for the purpose of issuing health certificates to travelers who wish to go into districts which have quarantined against other points unless the individual has a certificate of health.——Dr. Vernon Robins, bacteriologist to the Health Department has hatched out several genuine stegomyia mosquitoes from larvæ obtained from a small pond at the station of the Louisville and Nashville railroad.

Maryland.—Baltimore reports the stegomyia present.

Mississippi.—Jackson does not permit through passengers to change cars at the city station nor to get off a train for lunch.——Box cars are not permitted to stop in the city, whether disinfected or not.——The members of the Italian colony have been notified that if they permit any friends from other cities to visit them the entire colony will be held ten days in detention camp and then "put on the rock pile or in jail."——Vicksburg has guards patrolling the river front to prevent persons landing from boats, the guards being under orders to shoot anyone disobeying orders not to approach the shore.——Natchez is *incommunicado* with the entire world, and Jefferson, nearby, refuses to admit citizens of Natchez. Shotguns on both sides enforce the order.——Governor Vardaman commended the citizens of various towns who refused admission to fumigated freight from New Orleans.——The governor and various health officials of the state have bitterly accused New Orleans and the Louisiana State Board of Health of bad faith, double-dealing and concealment of cases of yellow fever.——Tupelo bars out passengers and freight from infected points.——Sardis, Oxford, Brookhaven, Hazelhurst and Terry have quarantines.——Canton admits no one without a ten-day health certificate, and forbids relays of train crews on the Illinois Central Railway.——Tutweiler, Oakland, Greenville, Nesbit, West Point and Granada are quarantined.——Dr. John F. Hunter, Jackson, secretary of the State Board of Health, on August 8 courageously announced that he regarded "shotgun quarantine as wholly useless," and urged that where in force they should be abandoned. He advised the people to turn their attention from quarantines to sanitation and to extermination of mosquitoes.——On August 10 the Board of Health announced that there was not a case of yellow fever in the state.——On August 16, 11 cases of yellow fever were found at Mississippi City and 5 more on the succeeding day. It is said cases have been concealed there since July 20. In any event Governor Vardaman says no more about the perfidy of New Orleans, and now advises all Mississippi communities fully to co-operate with the efforts of the Marine-Hospital Service and to accept its certificates.——A new case occurred August 21 at Mississippi City.——Governor Vardaman has arranged with members of the Legislature for authority to borrow $50,000, or as much thereof as may be needed, to meet the necessities of the epidemic and has pledged himself to use the funds as economically as possible. ——The suspicious case at Yazoo City was found by Dr. Wasdir, United States Public Health and Marine-Hospital Service, to be one of pernicious malarial fever.——Dr. Hicks, health officer of Vicksburg, on August 14 sent back to New Orleans a carload of sugar which had been partly unloaded before discovery. The board of health decided to prosecute the railroad for delivering the sugar.——There appears good reason to believe that the infection of Mississippi City did not come from New Orleans.

Missouri.—Three cases of yellow fever, with one death, were reported from Gregory, Mo., ten miles south of Keokuk, Iowa. The victims were Italians recently arrived from Greenwich, Miss. A spread of the disease in that section is not anticipated.——The St. Louis *Post-Dispatch* says: "Let us use the methods of science and civilization, not of ignorance and barbarism."——St. Louis will use a steamboat as a yellow fever hospital if cases occur.

Six of the Italian laborers quarantined at Gregory have escaped.——The health board of Keokuk has issued orders prohibiting trains or steamboats stopping at Keokuk.

New York.—A laborer recently returned from Panama, who was isolated in the Norwegian Hospital, Brooklyn, and reported to be suffering from yellow fever, is now declared to be suffering from tropical malarial fever, and his recovery is despaired of.——Dr. A. H. Doty on August 15 removed from the Mallory Line steamer *Concho*, from Galveston, ten persons having temperature above normal, and kept them under observation as suspects.

Oklahoma.—Guthrie decided not to quarantine, the mayor announcing his full acceptance of the results of the late Dr. Reed's work in Cuba.

Pennsylvania.—The Pennsylvania State Quarantine Board at its meeting at Marcus Hook on August 8, decided to establish quarantine against all ports south of St. Mary's, Ga., which includes all ports on coast and gulf from which an invasion of yellow fever is to be feared. It is considered that with the precautions taken at Marcus Hook, Philadelphia stands in no immediate danger of a visitation of the fever.

South Carolina.—Charleston fumigates cars, detains vessels from Central America, and requires five days' detention of persons from infected points.——The Board of Health of Columbia decided that quarantine was unnecessary.

Tennessee.—The Memphis and Shelby County Medical Society approved the quarantine as being demanded by the commercial bodies, but expressed its conviction that the disease is spread by mosquitoes.——Memphis permits through passengers to step from one train to another, but no more.——The Chattanooga quarantine is rigid and has been accompanied by various spectacular procedures. Through cars from Louisiana must have doors and windows closed and locked while passing through the city. Laundry operations have been restricted by fear of the workers getting yellow fever from Pullman car bed linen. One traveler said: "Knowing as we all do, that yellow fever is not even contagious without the mosquito inoculation, it is needless to say that Chattanooga is worth a visit just to see the fun." Another traveler wrote: "They were whirled at speed through Mississippi and Tennessee towns; there was no buffet or diner, and ice and water alike gave out. Neither conductor nor porter were permitted to leave the car at any station, and women and children were made to suffer 'sweatbox' punishment from closed sashes. In a high temperature this was often prolonged by switching off the sleeper and 'isolating' it a mile or so away, awaiting some through train to whirl the infected monster to the next insane town."—Memphis has had its quarantine troubles, and has finally ameliorated its conditions. One man secured a court injunction suspending the quarantine so far as his family was concerned.——Many trains have been annulled until travel is resumed.——It is alleged that politics played its part in the quarantine, the Board of Health being shorn of power, which was transferred to the chief of police.——Knoxville inspects all trains.——Brownsville keeps out everyone who has not a certificate from its county board of health.——Moscow ordained "that it shall be unlawful for any person to enter the corporate limits during the prevalence of yellow fever in the South."—It is said that the stegomyia abounds in Knoxville.——The Tennessee Legislature at its last session provided only a reduced epidemic fund of $5,000. Request has therefore been made of Surgeon-General Wyman to conduct train inspections with the corps of the United States Public Health and Marine-Hospital Service.——The Tennessee health authorities are endeavoring to arrange with Surgeon Young, United States Public Health and Marine-Hospital Service, and with the authorities of Mississippi and Arkansas for uniform certificates of health.——Memphis continues to kill mosquitoes and oil stagnant water.——Memphis has decided to permit passengers to transfer through the city, a detention car to be provided.

Texas.—Houston has a new mosquito ordinance, and oil has been supplied for pools, swamps, cisterns, etc.——Somerville is cleaning up and killing mosquitoes.——Jasper has a rigid quarantine.——It is proposed to inspect trains entering Texas from Indian Territory, to exclude refugees coming in by the roundabout way.——*The Texas State Journal of Medicine* scores those physicians who, disbelieving in the mosquito hypothesis, publish their dissent in the newspapers. It well says that such expressions are "pernicious, contrary to demonstrated facts, calculated to lessen medical influence, disturb public confidence, threaten commerce, and endanger human life."——As a matter of precaution the annual encampment of the Texas National Guard will not occur this year. ——The Texas Legislature provided no funds to fight disease and forbade the issuing of emergency certificates. The State Health Officer may therefore be compelled to accept public subscriptions in order to meet necessary expenses.

Virginia.—A strict quarantine against yellow fever was arranged for by the State Board of Health August 14. Correspondence from the Norfolk Board of Health was read setting forth the necessity of state action and the board determined on a vigorous method which is practically a quarantine against the infected districts. Inspectors will meet all trains at the state line and detain any suspected cases. Boats from the south will be subject to strict examination and quarantine regulations by the Norfolk authorities.

General and Foreign.

Cases to Date.—Up to the evening of August 20, 1,641 cases had been reported, with 221 deaths from 322 sub-foci of infection. On August 20, 61 new cases were reported in New Orleans and 21 outside of the city, making a total of 82, from 16 new sub-foci of infection, and 9 deaths.

Epidemic in Honduras.—It is reported that yellow fever is practically epidemic in Honduras, and that the disease appeared there simultaneously with the outbreak in New Orleans in May. It is believed that the disease was conveyed to Honduras by Italian freight handlers on the fruit steamers plying between there and New Orleans.

Panama.—Goverorn Magoon is supporting extraordinary efforts to perfect the proper sanitation of the Isthmus. Laborers have been withdrawn from other tasks for this purpose, and every effort is being made to assure sanitary camps, to get a good water supply into Panama, to erect hospitals, to fill in swamps and to cut down the underbrush about Colon and all the camps.

Record to August 23.—New cases outside New Orleans, August 22, 69; new deaths, 3; new cases in New Orleans, 57: new deaths, 9; new sub-foci, 21. In all 1,598 cases have been reported, with 230 *deaths*, a death rate of 14.4 per cent.

FOREIGN.

The Chair of Surgery in Leeds University.—Mr. Edward Ward, who has held the professorship of surgery in Leeds for the past six years, has resigned. He is to be succeeded by Mr. Harry Littlewood, M.Sc., F.R.C.S.

Cholera in Russia.—A dispatch from Europe states that cholera is still raging in several provinces on the left bank of the Vistula. The report states that the Russian censor has forbidden the publication of any details of the epidemic. Until now the frontier districts have not been affected.

International Congress of Hydrology.—The seventh meeting of the International Congress of Hydrology, Climatology, Geology and Physical Therapeutics will be held in Venice, Oct. 10, 1905. The general secretary is Dr. Fausto Oreffice, S. Stefano 2803, to whom all communications should be addressed.

International Exhibition in New Zealand.—The government of New Zealand, it is reported, has decided to hold an international exhibition at Canterbury from November, 1906, to April, 1907. One of the principal objects of the exhibition will be to demonstrate the resources of New Zealand as a food-producing country.

Summer Diarrhea Among Children in London.—A cable report from London, dated August 19, states that every hospital for children is full and that cases of summer diarrhea are being turned away because of lack of accommodation. There is reported to be a greatly increased mortality from this disease among children under 2 years of age.

The Plague Mortality.—It is reported that the plague epidemic has perceptibly declined. The Central Provinces, Central India and Rajputana are said to be free from the disease, but this is probably doubtful. The officers investigating the disease will remain in India till October. They are now engaged in research work in Bombay.

New Public Mortuary in Hong Kong.—The new public mortuary, which was completed in the early part of the year, is equipped so that the most varied pathologic research can be undertaken. The institution includes one research laboratory for the examination of rats and other animals, two large mortuaries, and two small laboratories for research work.

Epidemic of Sore Throat in London.—It is reported that hundreds of cases of sore throat have occurred in London. The disease is said to be slightly contagious. The first symptoms are slight hardness in the throat, which by morning has developed into a stinging pain. In some cases the Eustachian tube seems to be involved as a few patients complain of partial deafness.

Swimming in the Glasgow Public Schools.—For some time the Glasgow school board has given lessons in swimming in the public schools, and it is stated that these are much appreciated. Over 90 per cent. of the boys, receiving two lessons a week, were able to swim well after eight weeks, and about 50 per cent. of those receiving one lesson a week were fairly proficient in the same time.

Malaria in Italy.—The prophylactic administration of quinin is the distinctive feature of the campaign against malaria now being pushed into the Roman Campagna, under the auspices of the Italian Red Cross Society. During the month of June it is reported that 8,021 persons were given quinin in preventive doses. There were 168 cases of malaria in the section under observation, all of which occurred among persons who refused prophylaxis or were negligent in pursuing treatment.

Pure Milk Depots in England.—In an effort to check infant mortality the municipality of Leeds has decided to establish pure milk depots where the poor can obtain clean milk. The lord mayor has started a fund for this purpose with a subscription of $1,000. A committee has been appointed, composed of medical men, and the chairman in a letter asking for subscription refers to what has been done in America in this way. The committee intends purchasing milk from farmers whose cows are free from tuberculosis. It is intended that the cows shall be milked and the milk cooled and bottled under the immediate supervision of the employés or officials of the committee.

London Coroner Advocates Day Nurseries.—Dr. Waldo, the coroner for the city of London, is quoted as saying that the high death rate among infants and young children is largely due to ignorance and to involuntary neglect. Many women who are employed during the day leave their children to be looked after by neighbors, with the result that the children are often fed milk tainted with germs from the dust and refuse in the streets. The ignorance of mothers as to the proper way of caring for a baby or of feeding it, Dr. Waldo thinks, is also a cause of the high death rate. He states that he is in favor of the establishment of crèches near all large factories and workshops, where mothers can leave children in the care of a competent attendant and have them looked after properly on payment of a small fee.

An Antimalarial League in Greece.—An antimalarial league has recently been founded in Athens under the patronage of the king. The objects of the league are to disseminate knowledge concerning the results of modern malarial research among the people; to study the distribution of malaria and its special characteristics in the various districts; to draw up maps showing the marshes in each department; to remove pools in the neighborhood of houses; to investigate the means of drying up or of purifying the marshes; the destruction of mosquitoes; the introduction of mechanical means of protection of houses, etc.; the gratuitous supply of quinin, and the drafting of a bill providing for the carrying out of these objects and its presentation to the government. Professor Hadzimichalis, president of the Superior Health Council, is president of the league.

The Mission to Lepers in the East.—During the thirty years of its existence this mission has received about $850,000. Its first asylum was built in 1875 and it has now 42 asylums of its own while it aids 16 others. It has 20 homes for the untainted children of leper parents. This separation of healthy children, says the *British Medical Journal*, is one of the most important branches of the society's work in the struggle against leprosy. In addition to India, the society is active in various centers of Burmah, Ceylon, China, Japan and Sumatra. Several asylums in India have been transferred to its care, showing that the endeavors of the mission to lepers are appreciated on the spot, so much so that it receives considerable aid from the government. The medical side of the work is kept well in view. In many places fully qualified men are in charge of the asylums; in others there are hospital assistants, or helpers, with some medical knowledge. In the East there is no doubt that western medical influence is called on to play a preponderating part in the advancement of civilization.

Longer Period of Study for Indian Medical Students.—It was proposed to increase the period of study in the Calcutta Medical School from five to six years, but after the subject was thoroughly discussed it was decided to make no change, as a certain number of native medical men, supported by a limited portion of the native press, advised students to go to Japan and study rather than to Europe or Calcutta. One reason given for this advice is the reputed cheapness of study and of living in Japan, while at the same time it is argued that the education is equally good. It is forgotten, says the *Lancet*, that students who do not possess qualifications recognized by the government naturally have to shift for themselves as best they can in various forms of private practice. That a certain section of the native press should support such a proposal is not altogether astonishing and it is taken advantage of to attempt a sort of rebuff to British and European medical pretensions. In fact, the proposal was very inadequately considered on its merits and was chiefly made use of as a political move. The *Lancet* considers it very poor patriotism on the part of the Bengali "nation" to sacrifice its medical students for the sake of a very doubtful political snub.

Leprosy in China.—The Public Health and Marine-Hospital Service calls attention to a medical report, by Dr. Georges Brarbezieux, in the publication of the Chinese Imperial Customs, in which is described a remarkable focus of leprosy existing in Yunnan, the most southwest province of China. The report states that the number of lepers is very great and that they wander in the fields and about the streets of towns, frequenting abandoned pagodas and presenting the horrible stigmata of the disease. There are in Yunnan entire villages of lepers where the inhabitants live miserably on the products of rice fields. These persons have slight relations with the outside world, though they are free from the restraint of sanitary regulations and are not by any means ostracized. Nevertheless, they seclude themselves from the society of healthy persons, mingle with lepers only, and do not visit other villages except when the gravity of their disease renders labor impossible. When broken down physically by the progress of the disease they join themselves to more prosperous and healthy communities, and thus swell the immense army that lives in such places by public charity. With the advent of white men in Yunnan the number of leprous beggars has notably increased. It is estimated that in Yunnan there is one leper for every 100 inhabitants, but the concentration in certain parts of the country is still greater than the general figures indicate. There are no institutions, public or private, for the care of these unfortunates, and the disease is not considered to be more than very slightly, if at all, contagious.

LONDON LETTER.

Goats and Malta Fever.

An important discovery seems to have been made with regard to the propagation of Malta fever. About twelve months ago a commission was appointed by the admiralty, the war office and the civil government of Malta for the purpose of inquiring into the prevalence of Malta or Mediterranean fever among the naval and military forces and the general population of Malta. The commission originated in a letter sent by the colonial secretary to the Royal Society in which he drew attention to the prevalence of the fever and invited the society to nominate a commission of investigation. This was done, and Colonel Bruce of the army medical department (who in 1887 discovered the microbe of Malta fever, the *Micrococcus melitensis*), was appointed chairman. For some time the committee has been engaged in pathologic investigations of an extended character. A series of epidemologic inquiries were conducted in the Maltese Islands by Dr. R. W. Johnstone, one of the medical inspectors of the local government board. Then attention was directed to the milk supply. In Malta the usual source of milk is the goat, flocks of which are driven about the streets to be milked at customers' doors. Two members of the commission, Dr. Zammit and Major Horrocks, have determined experimentally that goats are susceptible to Malta fever. Hence they infer that the disease may be spread to man by the medium of milk. Numerous tests showed that some of the goats in every herd examined were suffering from Malta fever, and that the micrococcus is excreted in the milk in enormous numbers when the disease has existed long enough to bring about a change in the physical character of the fluid.

The King's Hospital Fund: Permanent Income of $250,000 Secured.

The King's Hospital Fund was founded in 1897 by his majesty when Prince of Wales, who saw in the scheme a striking way of commemorating the sixtieth year of the reign of the late queen. In the first eleven months of its existence $1,100,000 was paid into the fund, and this has been increased each year until at the end of 1903 the total amounted to $5,500,000. The awards paid to the various London hospitals have amounted to $2,500,000, and more than $3,300,000 has been invested. As the result of some recent gifts and bequests the fund has now reached such a capital amount that a permanent income of $250,000 is secured—the object at which the trustees have been aiming for some time. All the hospitals within a radius of seven miles from Charing Cross or within the area of London County Council are entitled to share in the benefits of the fund, which since its foundation has been instrumental in opening no fewer than 443 free beds.

The Government and Industrial Mercurial Poisoning.

The government has issued a memorandum reminding medical practitioners that they must notify the chief inspector of factories of every case of mercurial poisoning contracted in a factory or workshop. Proper notification forms for this, as also for anthrax, for poisoning by lead, phosphorus or arsenic are supplied. Factory surgeons are obliged to investigate and to report on all cases of mercurial poisoning brought to their knowledge, and in certifying children and young persons for employment in industries in which mercury is used they are reminded of the undesirability of young persons being employed in mercurial processes, not because they are more susceptible to the poison, but because of their probable inattention to the necessary precautions. Fifty-six cases of mercurial poisoning were reported between May, 1899, and Dec. 31, 1904. They occurred in the following industries: Manufacture of thermometers, 15; electric meters, 15; hatters, furriers, 10; chemical works, 7; water gilding, 5; powder factories, 3; photoengraving, 1. Factory surgeons have power at their periodical medical examinations to suspend not only workers showing signs of poisoning, but those who, by inferior physique, indulgence in alcohol, careless habits and want of attention to the regulations, show a liability to mercurial intoxication.

The Quatercentenary of the Royal College of Surgeons of Edinburgh.

With fitting pomp the Royal College of Surgeons of Edinburgh has celebrated its quatercentenary. The celebration began by a service in St. Gile's Cathedral, which was attended by a large and brilliant gathering. The honorary fellows-elect, who included distinguished surgeons from all parts of the world, among whom were the American professors Halsted, Keen and Howard Kelly, the fellows and a representative company of guests marched in procession to the cathedral. The commemoration ceremony was held in the afternoon and was attended by representatives of other colleges, of various universities and of learned bodies. Sir Patrick Heron Watson, the president, delivered a short address of welcome in which he sketched the history of the college. Its origin as a corporate body may be traced to the reign of James IV of Scotland, who in 1506 confirmed the royal charter which a year previously had been granted to the barber-surgeons resident within the borough of Edinburgh by the provost, bailies and council of the borough. There is reason to suppose, however, that previously an organized body of practitioners existed to whose desire for authority to practice the college is indebted for its inception. The honorary fellowship was then conferred on a number of distinguished foreign and British surgeons. A banquet was held at which 350 were present. The president was accompanied by the lord provost of Edinburgh, the French ambassador and other prominent officials and distinguished guests.

"Costly Medical Errors."

Under this and similar titles the lay press waxes very indignant at errors in diagnosis made by physicians who have sent patients to the London fever hospitals. It appears that during 1904, 21,000 cases of scarlatina and 538 cases of smallpox were admitted to these hospitals, and that also nearly 2,000 cases of mistaken diagnosis occurred. The average period of detention in these latter cases was a little over three weeks and the expenditure represented $60,000. The chairman of the statistical committee of the hospitals said that this expenditure ought never to have been incurred and that these patients should never have been sent to hospit How infallibility of diagnosis is to be secured he did not explain.

The Proposed Amalgamation of the London Medical Societies.

The executive committee of representatives of the London medical societies, appointed to consider a scheme of amalgamation, as mentioned in The Journal, May 6, 1905, page 1461, has presented a report. The committee appointed chartered accountants to investigate the rolls of membership and the accounts of the principal 22 London societies. These were found to have a membership of 7,229, composed of 4,997 persons. Of these 3,725 are members of only one society and the remaining 1,272 are members of more than one society. The balance of assets over liabilities (including certain bequests and trust funds) is more than $200,000. If 3,800 members of societies other than the Royal Medical and Chirurgical Society become members at a subscription of $5 per annum the new society will have a small balance of income over expenditure. If any members of these societies become fellows at a subscription of $15 the balance will be increased. This estimate is based on the present income and expenditure of the Royal Medical and Chirurgical Society and the income and expenditure of 17 other societies, and makes no allowance for any economics which may be effected by the union. The present income of the Royal Medical and Chirurgical Society is $25,000; its expenditure is $21,500. In view of the facts that 3,525 persons already subscribe $5 each to the other societies and that 1,272 pay from $10 upward, it is thought that the new society will have a sufficient balance of income over expenditure to provide for improvements and for any sinking fund rendered necessary by extensions of the premises of the Royal Medical and Chirurgical Society. The committee made the following suggestions: 1. The new society shall be called the Royal Society of Medicine, or the Royal Academy of Medicine, according to the vote of the societies concerned. 2. It shall be housed at 20 Hanover Square, the present premises of the Royal Medical and Chirurgical Society. Increased accommodation can be obtained by extending the premises and by the absorption of certain rooms now occupied by tenants. 3. The society shall meet four or more times annually to discuss subjects of medical and scientific interest. 4. The society shall consist of the following sections, with power to add new sections or to modify the existing ones: 1, Anesthetic; 2, clinical; 3, dermatologic; 4, diseases of children; 5, epidemiologic; 6 laryngologic, otologic and rhinologic; 7, medical; 8, mental medicine (psychiatry); 9, neurologic; 10, obstetric and gynecologic; 11, odontologic; 12, ophthalmologic; 13, pathologic; 14, state medicine; 15, surgical; 16, [illegible] general therapeutics, pharmacology, [illegible] lneology and climatology. It is hoped t[illegible] e an anatomic and physiologic section will be formed. 5. The society shall consist of fellows, members, honorary fellows and honorary members. The fellowship shall be restricted to those practitioners whose scientific attainments are satisfactory to the general council. 7. A fellow shall pay annually $15 and shall have the right to attend all meetings of the society or any of its sections, and shall have the full use of the library. 8. Each section shall have power to elect as members of the society such persons as the council of the section shall think fit, provided that the names be previously submitted to the council of the society for approval. 9. A member of any particular section shall pay annually $5 and shall have the right to attend all the meetings of his section, but must pay an additional $1 annually if he wishes to use the library, and a further subscription of $2.50 for each additional section. 10. The general management of the society shall be under the control of a general council consisting of the president, the presidents of the various sections, two treasurers, two librarians, two secretaries and eight other fellows. 11. A monthly publication shall be issued except in the months of July, August and September, and be called "The Proceedings of the Royal Society of Medicine." It will be under the control of an editorial committee and will contain a record of the work of each section during the previous month. In addition the committee will select, subject to the approval of the general council, such papers as they may consider worthy of publication in the transactions of the society. The committee further suggested that it would be an advantage to form a committee of representatives of the various sections to receive all papers to be read. This committee would have power to decide before which section a paper should be read and whether other sections of the society be asked to join in the discussion. The committee concludes that the union of the medical societies will do much to enhance the prestige of British medicine and to increase the value of the work carried on by the existing societies, and that it will be a great convenience to the profession.

The Increase of Suicide.

At the Medicolegal Society Dr. Wynn Westcott, coroner for Northeast London, read an important paper on suicide. He found that inquest juries bring in only about 1 per cent. of suicides as guilty of *felo de se;* in cases where there is no evidence of the mental condition of the person they attribute the act to temporary insanity. He said that patients are often prematurely discharged from asylums and in the exigencies of home life slay themselves. Of predisposing causes alcoholism is the most common, then the presence of disease. An additional grievance or an overmastering passion, he stated, is usually the proximate cause. The relation of the sexes is very constant—three men to one woman. The rate of suicide per million of the population is constantly increasing; thus in 1861 it was 66; in 1881, 77; in 1891, 85; in 1901, 96, and in 1903, 105.

Correspondence

The Yellow Fever Epidemic.

NATCHEZ, MISS., Aug. 15, 1905.

To the Editor:—In THE JOURNAL, August 12, you did a palpable injustice to some of the best people in the South when you refer to the quarantines as relics of the middle ages. Please let me call your attention to the report of the president of the Louisiana State Board of Health, in which he admits that he was aware of the existence of the fever on the 13th, but waited eight days before admitting it, thus allowing the people from the infected area time to scatter all over the states of Alabama, Mississippi and Louisiana. It is this continued failure to keep faith with the people that has forced the present harsh measures. We know that non-intercourse with infected areas will prevent the introduction of the disease into the healthy towns, and propose to follow up the plan that has proved safe in other times. We have had two small epidemics here; in both cases the infection was brought here when there were no reported cases in New Orleans. We lost some of our best people each time, and the fever spread in spite of every known method of checking its progress.

I have had considerable experience in the treatment of the fever though not an immune, and I may tell you that I am unable to prevent the mosquitoes biting either myself or the patients. My own house is screened throughout with the finest of wire screens, and each bed has the very best mosquito netting, yet in spite of all these precautions we have to endure the annoyance and stings of these pests. All southern people know these things, and for this reason they seriously doubt the possibility of checking the spread of the infection by means of screens. They know the practical impossibility of preventing the patient being bitten.

As to the quarantines: We do not enjoy them at all ourselves. They almost destroy trade and prevent business of all kinds. But we can not help ourselves. We do not know where the infection has spread, so a policy of exclusion is being practiced. We harm no one; simply say to them, "For the present please stay at home." If you will come here and visit us, and let us show you our death records, we are sure that you would favor anything that gave promise of safety from this pestilence.

It may be that some reporter allowed his imagiantion to run away with his regard for the truth, and to that report you referred. But to my mind, the people have acted with great forbearance, considering the vast amount they had at stake. We do all in our power to render the six days' detention as pleasant as possible to all concerned. But this city is certainly closed to the world for the present. If it were not so, persons leaving New Orleans could go direct to Chicago, procure a health certificate, and be here in less than three days.

I trust that you will publish this little note, and you can refer to the issue of THE JOURNAL for August 12 for the report of Dr. Souchon to which reference is made.

J. C. BALLARD, M.D.

An Indorsement of Governor Pennypacker by Philippine Islands Medical Association.

MANILA, P. I., July 12, 1905.

To the Editor:—By direction of the Committee on Public Policy and Legislation of the Philippine Islands Medical Association, I have the honor to forward a copy of a resolution tendering a vote of thanks to Governor Pennypacker of Pennsylvania for the service which he has rendered the medical profession of the world and the people of his state in withholding his signature from the bill passed by the legislature to legalize and regulate the practice of osteopathy in Pennsylvania.

Governor Pennypacker has evidently given the subject of class legislation more study than is usually bestowed on it by chief executives, as is shown by his clear understanding of those principles of ethics and justice for which the medical profession has always stood.

He could have rendered his people no greater service than that which has been accomplished by his veto which may truly be called "A veto for the protection of the people of Pennsylvania from the evils of legalized quackery."

Very respectfully,

R. E. L. NEWBERNE.

Secretary-Treasurer, Philippine Islands Medical Association.

RESOLUTIONS.

WHEREAS, It having come to the knowledge of the Committee on Public Policy and Legislation of the Philippine Islands Medical Association, through the editorial pages of THE JOURNAL of the American Medical Association, that Governor Pennypacker of Pennsylvania has vetoed the bill passed by the legislature to legalize and regulate the practice of osteopathy in that state; and

WHEREAS, The reasons given by the governor for his course are so manifestly just and fair, it was, on motion,

Resolved, That the Committee on Public Policy and Legislation of the Philippine Islands Medical Association tender a vote of
thanks to the governor of the commonwealt
the careful study which he has given this
for the just, courageous and scholarly stan
in the interest of science and justice, and
the people against the evils of class legislati

Resolved, That the secretary of the committee be instructed to forward copies of the resolution of the committee to Governor Pennypacker and to THE JOURNAL of the American Medical Association.

Finsen's Light Institute.

COPENHAGEN, July 11, 1905.

To the Editor:—After a week spent at Finsen's Light Institute I have begun to realize the magnitude and extent of the work performed here. Each day from 150 to 200 patients receive treatment, among whom one can recognize types from all civilized nations. The institute itself is situated in a quiet part of Copenhagen, the streets leading thereto being amply provided with shade trees which produce a pleasing and restful effect as one approaches the buildings. The institute physicians, four in number, are well trained and courteous. The government annually subscribes 30,000 kroner toward the maintenance of the institution. This, together with the Nobel prize money which Finsen munificently tendered the institute, has rendered possible its present complete organization.

All who seek treatment obtain it. Those who can afford to pay do so, and those who can not afford to pay receive treatment gratis. A school is also maintained for the children who are compelled to undergo treatment for a long time. Much compassion is shown the poor unfortunates who come disfigured with disease, and they are treated most kindly by physicians and nurses alike. From 8 to 11 a. m. every day the physicians are at work in their large, well-lighted clinic room, examining new patients and treating by topical applications and the galvanic cautery such lesions of the nasal and oval cavities as are inaccessible to the lamp treatment. In this room the doctors indicate with pencil by marking circles around the various lesions which are to be exposed to the chemical light rays that day. Thus is the progress of each patient watched and directed daily.

From the clinic the patient is conducted to the laboratory for light treatment. Here are eight large 50-ampere arc lamps, each lamp being equipped with four projectors containing lenses and cooling devices to accommodate four patients. Thus 32 patients can be treated at one time, each patient being under the immediate care of a separate nurse who applies the light. Several other lamps are placed in smaller rooms where more privacy is obtained. The current supplied by the city is 500 volts direct. This being too high for safety, is used to actuate a motor which in turn drives a dynamo that delivers a 70-volt direct current. This current supplies the energy for all the apparatus.

With the patient placed on the table, the area which has been pencil-marked by the physician is brought to focus under the light, and with a compressor lens over the lesion, is exposed for one hour and ten minutes. In twenty-four hours a strong reaction is visible where the light has acted, vesicles form which take from six to ten days to heal up. If this exposure has not been sufficiently strong to destroy the active lesion another is given, and so on, one treatment every eight or ten days until the disease is vanquished. If the disease is extensive different regions are exposed daily.

The conditions which yield best to the light treatment are lupus vulgaris and erythematosis, acne, small non-elevated angiomata or port-wine marks, and very superficial epithelioma. For these diseases and conditions the chemical light treatment as carried out here is as near specific as anything medical or surgical can be within the meaning of that word. For ordinary or deep-seated epithelioma the Roentgen rays are used. For this purpose a 20-inch Rumkorff induction coil is provided, with mercury turbine interruptor on the 70-volt direct current. Twenty-minute exposures are made and repeated when reaction permits. Patients suffering from lupus erythematosis are given in addition to light treatment from 20 to 30 centigrams of quinin daily.

The results obtained here can be ascribed to efficient apparatus, and, more important yet, correct technic and patience. The rooms of the institute are open to the physicians of the world, who can see for themselves and judge; nothing is kept hidden. The management of Finsen's Institute desire to have it known that they have no connection whatsoever with a so-called Finsen Institute of America, located, I believe, in Chicago and widely advertised in the daily press.

Albert Soiland, M.D. (Los Angeles).

Marriages

William G. Doern, M.D., to Miss Reeves, both of Fort Madison, Iowa, August 15.

Walter F. McCabe, M.D., to Miss Anna M. Moe, both of Beloit, Wis., August 12.

Thomas Garton Kell, M.D., Pineville, N. C., to Miss Marie Laura Delmas of Pascagoula, Miss., August 9.

Reginald M. Burdon, M.D., Green Bay, Wis., to Miss Louise Lange of Houghton, Mich., August 16.

Louis F. Baker, M.D., to Mrs. Nellie S. Appleby, both of Fitchburg, Mass., in New York City, August 11.

David James Graham, M.D., Edinburgh, Scotland, to Miss Ethyl Gray of San Francisco, in New York City, August 9.

George J. Koch, M.D., to Miss Josephine Fitzmaurice, August 9.

Francis E. King, M.D., to Miss Mary Owens Randall, at Baltimore, August 14.

Treston R. Ayars, M.D., to Mrs. Fannie Hamilton Shedd, both of St. Louis, August 16.

Charles L. Large, M.D., Forest Grove, Ore., to Miss Edna L. Hicks of Fairmount, Minn.

Deacon Steinmetz, M.D., to Mrs. Ellen Fagan Crosby, both of Philadelphia, August 14.

Frank Dyer Sanger, M.D., Baltimore, to Miss Grace Hamilton Hague Cochran, August 9.

George H. Ehrhorn, M.D., Tea, S. D., to Mrs. Florrie B. Dales, at Anniston, Ala., August 3.

Robert Lee Schorr, M.D., to Miss Mabell Stanley Leonard, both of Detroit, Mich., August 23.

Harry C. Parker, M.D., Boston, to Miss Clara Margaret Parker of La Grange, Ill., August 16.

William C. Arons, M.D., Hudson, Wis., to Miss Mary C. MacMurdy of Aitkin, Minn., August 4.

George M. Livingston, M.D., Manistique, Mich., to Miss Mabel A. Joy of Albion, Mich., June 28.

Marcus Harold Merchant, M.D., to Miss Alice Louise Gardner, both of Warren, R. I., August 14.

Charles Wallace Ransom, M.D., Brooklyn, Wis., to Miss Myrtle B. Richards of Beloit, Wis., June 14.

Harry Hamilton Snively, M.D., Columbus, Ohio, to Miss Florence Knowlton of Plymouth, Ohio, August 15.

Harley Sylvester Herrick, M.D., Westford, Vt., to Miss Florence Amelia Holyoke of St. Albans, Vt., August 2.

Lillian B. Eshleman, M.D., Battle Creek, Mich., and Prof. Percy Taylor Magan of Unavara, Madison, Tenn., at Cherokee, Iowa, August 23.

Deaths

Samuel Wilson Trimmer, M.D. Philadelphia College of Medicine and Surgery, 1854, a prominent physician and politician of Luzerne County, Pa., some-time prothonotary and oil inspector of the county; a member of the National Association of Railway Surgeons, Luzerne County Medical Society and Lehigh Valley Medical Society, died at his home in White Haven, July 31, from angina pectoris, after an illness of several weeks, aged 71.

Clarkson C. Schuyler, M.D. Albany (N. Y.) Medical College, 1875, member of the Clinton County Medical Society, for 14 years consulting surgeon to the Troy Hospital, member of the Association of Military Surgeons of the United States, and state forest commissioner from 1893 to 1895, died from cirrhosis of the liver at his home in Plattsburgh, N. Y., August 16, aged 55.

John H. Stringfellow, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1845, known as the father of Atchison, Kan., speaker of the first Kansas House of Representatives, and founder of the *Squatter Sovereign*, the first newspaper published in that state, died at his home in St. Joseph, Mo., July 29, from pneumonia, aged 86.

Henry D. Stauf, M.D. Missouri Medical College, St. Louis, 1885, of St. Louis, who wandered away from home when ill July 28, is supposed to have fallen into the Mississippi River and been drowned on that day, aged 42. His body was taken from the river at Barrow, Tenn., August 12.

Robert Marsena Stone, M.D. New York, 1874; St. Louis College of Physicians and Surgeons, 1884; a member of the American Medical Association; a prominent practitioner of Omaha, who had made a special study of anesthesia for many years, died at his home in Omaha, August 14, from nephritis, after an illness of several weeks, aged 58.

Otto Negelspach, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887, was killed instantly at his home in Millersburg, Ohio, August 14, by touching a broken telephone wire which had crossed an electric light wire, aged 37.

Andrew Carr Kemper, M.D. University of Louisville Medical Department, 1866, who served throughout the Civil War as surgeon, for the most part on the staff of General Halleck, died at his home in Cincinnati, August 15, aged 73.

W. Dalton Deshazo, M.D. University College of Medicine, Richmond, Va., 1905, of Stokesdale, N. C., died at the home of J. P. McMichael, near Madison, N. C., August 11, from typhoid fever, after an illness of three weeks, aged 24.

Samuel D. Tracy, M.D. Barnes Medical College, St. Louis, 1899, of Odin, Ill., president of the Southern Illinois Medical Association, died at the Olney Hospital, August 11, from typhoid fever, after a lingering illness, aged 29.

Robert Hugh Cooke, M.D. Starling Medical College, Columbus, Ohio, 1858, a surgeon in the Army during the Civil War, who retired from practice in 1866, died at his home in Grayville, August 6, after a long illness, aged 73.

John Van Vliet, M.D. Ensworth Medical College, St. Joseph, Mo., 1880, died at his home in Wheaton, Kan., August 7, from the effects of carbolic acid self-administered while despondent over long-continued ill health, aged 52.

J. L. Thigpen, M.D. Medical Department of the University of Georgia, Augusta, 1881, died at his home near Pineview, Ga.. August 4, after a period of invalidism, due to cerebral hemorrhage, of four or five years, aged 68.

Francis Marion Setzler, M.D. Medical College of the State of South Carolina, Charleston, 1862, died at his home, near Whitmire, S. C., July 29, from disease of the stomach, after an illness of six months, aged 60.

W. S. Duncan, M.D. Illinois Army Board, 1864, (Years of Practice, Illinois), 1884; assistant surgeon Tenth Illinois Volunteer Cavalry in the Civil War, died at his home in Greenup, Ill., August 2, aged 80.

E. R. Weaver, M.D. Tennessee Medical College, Knoxville, 1892, of Highland Park, Chattanooga, Tenn., died at Erlanger Hospital in that city, August 4, after an illness of five weeks, aged 45.

Kimball David Webster, M.D. Vermont Medical College, Woodstock, 1837, said to have been the oldest practitioner in New Hampshire, died at his home in Gilsum, N. H., August 9, aged 94.

Harriman Couch, M.D. (Years of Practice, Illinois), 1879, said to have been the oldest practitioner of Peoria, Ill., died at St. Francis' Hospital in that city, August 18, after a long illness.

Frederick C. Hall, M.D. Medico-Chirurgical College of Philadelphia, 1894, died at his home in Scranton, Pa., August 14, from septicemia contracted in an operation six years before.

Joseph D. Wade, M.D. Medical College of the State of South Carolina, Charleston, 1857, died at his home in Marshallville, Ga., August 2, after a long period of decline, aged 72.

John H. King, M.D. University of Maryland School of Medicine, Baltimore, 1872, of Pocomoke City, Md., died at Ocean City, Md., August 12, from heart disease, aged 47.

Robert Patterson Robins, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1880, of Philadelphia, died at Sharon, Conn., August 13.

Wilfred J. Labelle, M.D. Laval University Medical Despartment, Quebec, 1895, died suddenly at his home in Swanton, Vt., August 9, from heart disease, aged 33.

John W. Holloway, M.D. University of Louisville Medical Department, 1850, died at his home in Nicholasville, Ky., from senile debility, August 14, aged 82.

Robert J. Clark, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868, died at his home at Chestnut Level, Pa., August 19.

Nathan M. Scales, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1860, died at his home at Vose, Ky., August 18, aged 67.

Cornelius C. V. Crawford, M.D. Jefferson Medical College, Philadelphia, 1863, of Camp Ground, Pa., died at Atlantic City, N. J., August 16.

D. H. Patchen, M.D. Illinois, 1879, of Fremont, Ind., was found dead in a hotel at Walcott, August 10. The coroner's verdict was suicide.

Samuel Sherbourne, M.D. Long Island College Hospital, Brooklyn, N. Y., 1882, died at his home in Philadelphia, August 14, aged 71.

James A. Murray, M.D. Chattanooga (Tenn.) Medical College, 1894, died at his home in Glenalice, Tenn., August 9, from pneumonia.

George E. Smith, M.D. Medical College of Ohio, Cincinnati, 1862, died at his home in Oberlin, Ohio, August 3.

Samuel J. Brown, M.D. Missouri, 1896, died at his home in Beaumont Station, Mo., August 14, aged 39.

Rudolf Bestle, M.D. Albany (N. Y.) Medical College, 1888, died at his home in Hunter, N. Y., August 9.

I. C. Truett, M.D. (Certificate, Tennessee), 1896, died at his home in Livingston, Tenn., July 29.

Book Notices

TREATISE ON PLAGUE, Dealing with the Historical, Epidemiological, Clinical, Therapeutic and Preventive Aspects of the Disease. By W. J. Simpson, M.D. Cloth. Pp. 466. Price, $5.00. Cambridge: The University Press. 1905.

The contents of the book are divided into four principal parts: history and distribution of plague; epidemiology of plague; plague in the individual; measures for prevention and suppression of plague. There are two appendices, one giving the deaths from plague in India in 1904 and one giving the provisions of the International Sanitary Convention at Paris, 1903. There are maps, charts and illustrations of buboes, etc. "Few thought it possible, when plague broke out in Bombay in 1896 after an absence of 200 years, that the disease would not be controlled, checked and stamped out in a short time. It was a rude awakening when deaths began to mount up to a few thousand to find old scenes associated with plague epidemics reappear. The closed houses, the deserted streets, and nearly half of the population fleeing panic-stricken from the city, testified to the fact that plague had lost none of its old horrors. . . . The next year and every year since 1896, the disease has recrudesced in Bombay, and the number of deaths is fast mounting up beyond the mortality of any epidemics of plague in any single city in the past with the exception of those of Constantinople and Grand Cairo. And still the disease continues. Plague has moreover spread from Bombay to the Bombay Presidency, and from the Bombay Presidency to a large portion of India. Slow in its progress it has steadily advanced; and now the 30,000 deaths from plague which occurred in India in the past year, and which created so much alarm, has reached during the past two years over three-quarters of a million per annum. In 1903 the number of deaths from plague in India was 853,000, and in 1904 it was over a million, being 1,040,429. . . . The total number of deaths in India officially recorded from plague since 1896 was, up to the end of December, 1904, 3,150,000." Do not these statements from the preface come as a shock to most of us? The book is written with the organization of a high grade Indian public health service in mind, which is regarded as essential for the establishment of proper and effective preventive measures. At the same time plague in its various aspects is considered in such a way as to interest and greatly instruct all that are in any way concerned about this disease. The importance from the point of view of a prevention of conjoint action on the part of those engaged in research and of those engaged in administration is clearly recognized and stated. In the seventh century two kings of Erin summoned a council at Temora because the land was not sufficient to support the population. The chiefs decreed that a fast should be observed so that they might with one accord solicit God to remove by some species of pestilence the burthensome multitudes of the inferior people. And a pestilence did come; it removed the authors of the petition, the two kings and a third of the nobles concerned. This sounds passing strange to us at this time, but there are those even now who hold that plagues are necessary to keep down populations that otherwise would perish by hunger. This doctrine is easy-going and would lead to the saving of much trouble; for to prevent the spread of plague in India demands strenuous statesmanship as well as organized sanitary service. In the meantime the condition of the people of India in the worse affected provinces is most deplorable. "It not only claims the deepest sympathy, but also in the interests of humanity imperatively demands the closest attention. . . ." Dr. Simpson's book does not appear to be the product of an alarmist, but of an earnest, practical sanitarian, with broad views, and his treatise should be in the library of all students of preventive medicine.

ACUTE CONTAGIOUS DISEASES. By William M. Welch and Jay F. Schamberg, M.D. Illustrated with 109 Engravings and 61 Full-Page Plates. Cloth. Pp. 781. Price, $5.00. Philadelphia: Lea Bros. & Co. 1905.

This book deals with vaccinia, smallpox, chickenpox, scarlet fever, measles, typhus fever, diphtheria and disinfection, i. e., the diseases that by virtue of extreme contagiousness require isolation and treatment in special hospitals. Nearly one-half of the 781 pages are given over to the discussion of smallpox and allied subjects, e. g., vaccinia and varioloid diseases in lower animals. Vaccination in all its phases is considered with great thoroughness. Dr. Welch's long personal experience with smallpox is drawn on freely and instructively, and nothing but satisfaction can be expressed with the presentation of the various topics regarding it. Our knowledge concerning this disease is here summarized in an attractive and serviceable manner and with interesting references here and elsewhere as well to the older literature on the subjects discussed. We believe, however, that the authors are a little prematurely skeptical concerning the value of the red-light treatment of smallpox advocated by Finsen. The necessity of actually demonstrating that the actinic rays are excluded completely in so-called red-light wards before any opinion may be formed as to the value of the treatment is not emphasized; furthermore, nothing is said of the limitations of the treatment outlined by Finsen, namely, that it must be begun before the fourth or fifth day of the disease.

Scarlet fever is given adequate consideration. No definite stand is taken as to the vexed question of the etiology of this disease. Most of the advocates of the streptococcal nature of the disease are cited, with some notable omissions (Moser and others). The views as to the value of antistreptococcus serum in the treatment appear conservatively sane. The extensive literature in regard to scarlet fever has been reviewed with great care. About 90 pages are given to the treatment of diphtheria. The antidiphtheric serum is given first place and a large amount of statistics bearing on the results are presented. The last chapter deals with disinfection. The illustrations are mostly of the various eruptions and rashes of the contagious disease. In the index we note that the names of the authors quoted in the text are omitted. The reviewer believes that it is of advantage in works of this nature to index the names of authors. The book is recommended heartily to physicians for guidance and information with respect to the important diseases of which it treats.

A Manual of [illegible] s and Practitioners. By H. Jellett, B.A [illegible], with the assistance in special subjects [illegible] F.R.C.P.I., Medical Super- [illegible] Drury, M.D., F.R.C.P.I., Dublin; T. G. Moorhead, [illegible] Royal City of Dublin Hospital, Dublin; [illegible] Pathologist to the Rotunda Hospital and to Dublin. With 476 Illustrations. Cloth. New York: William Wood & Co.

In times past it was the popular belief that all things British gave evidence of their insular opinions. The work of Henry Jellett, of Dublin, would most emphatically refute any such opinion, if held. A perusal of his manual of obstetrics will impress all with the cosmopolitan character of the presentation of the material embodied in the volume. We may say with positiveness that no British obstetric writer has so broadly interpreted the work of the foreign authorities as has Dr. Jellett; the recognition of American writers is particularly frequent. From first to last one finds constant pleasure in reading the various topics. The style is easy, entertaining, and the writer has not entered into pedantic discussions; the matter is sufficiently concise for students, yet amply broad for the practitioner; the work has been so brought up to date that the latter will find much to attract him, while the former will receive a thorough foundation in the principles and practice of obstetrics. To cover the innumerable virtues of the book would necessitate a mention of nearly every topic discussed. The parts of the volume which deserve special commendation, if they may be given a preference, are the physiology of pregnancy, labor and the puerperium, and the consideration of chorio-epithelioma in the pathology of pregnancy. Special mention must be made of the obstetric operations, the presentation of which is eminently fair, free of all dogmatism of statement, and abundantly adequate for the needs of those for whom the manual is primarily intended. Certain aspects of the volume appear faulty to an American. We can not agree with Dr. Jellett in his recommendation of the Dublin method of conducting the third stage of labor if he has correctly described it; the technic of the Dublin method is not that of Credé; therefore, we can not accord priority to the rotunda for the proper technic of fundal placental expression, for Credé has suggested a material improvement. Dr. Jellett describes the Dublin method as follows: The ulnar surface of the hand should be placed behind the uterus, and expression be consummated by a downward and backward movement as the uterus is compressed from side to side. We believe this is dangerous teaching for two reasons: First, the "side-to-side" compression means the production of an actual cavity within the uterus, which does not physiologically exist, with the possibility of causing an aspiration of air—a danger which he himself mentions in the discussion; secondly, the more valid objection lies in the fact that lateral compression may produce a dangerous injury to the tubes and ovaries. We believe traction on the cord deserves no mention in a modern obstetric work as a means of delivering the placenta beyond a most unequivocal condemnation. We regret the omission of all mention of the disposal of the pubic hair in his discussions of surgical cleanliness; to say the least it is inconsistent to demand the routine shaving in gynecologic work and to omit its mention in connection with obstetric surgery. In the discussion of the treatment of eclampsia we feel that too great stress is laid on the administration of sedatives and emptying the uterus without a direct correlation of the eliminative treatment. The exhibition of chloral, bromids, morphia, and chloroform are not curative measures, are merely empirically applied expedients. Elimination is the *sine qua non* and should be most prominently brought forward in connection with all other therapeutic measures until we have a specific therapeusis. The treatment of asphyxia neonatorum is insufficiently stated, being practically limited to Schultze's swinging and Hall's maneuver, two methods formerly much in vogue, and the former still recommended with unvarying regularity. The dangers of Schultze's swinging—the rapid cooling of the body (retention of heat being a most essential requisite), the great danger of producing fractures, if not mortal injuries, the liability of causing aspiration of mucus, and, finally, the necessity of violent exertions on the part of the manipulator, leave little to recommend the procedure. We find no mention of Byrd's, Bruist's, Prochownik's, Laborde's methods, and the most convenient plan of rhythmic compression of the chest while the trunk of the child is submerged in a warm bath. The illustrations generally depict the descriptions of the text and are well executed; they truly illustrate the work.

Multiple [illegible] vestigation Into the Nature [illegible] Sidis, M.A., Ph.D. (Harvard), [illegible] tion and Psychopathologic R [illegible] A.B. (Yale), M.D. Cloth. Pp. [illegible] D. Appleton & Co. 1905.

This work is in three parts. In the first, by Dr. Sidis, the subject of personality is treated, the author going through the various types of life to illustrate the development of the individual consciousness. This, of course, is largely psychologic, the view being held that as the organizations pass upward on the scale they become more complex and the possibilities of dissociation more numerous. The constitution of the individual mind, according to the author, is made up of many subordinate individual minds less complex in their nature. There may be, he says, "as many different personalities, parasitic or secondary, as there are possible combinations and disaggregations of psychophysiological aggregates. There may, therefore, be different forms of secondary consciousness or of multiple personality. These may be of a simultaneous character or one of alternation. The personalities may appear side by side or they may appear alternately. The play of personality may be of a dramatic character, the characters and personality appearing on the scene of consciousness like so many actors, the whole appearing as a play of many different persons." In other words, passing upward from the simplest individual consciousness of the lowest organism with a neuron the author finds the highest complications of neurons still a bundle of disagreeable consciousnesses or personalities. Thus in certain conditions and in certain peculiarly constituted individuals, the whole higher system of cells and association fibers may be switched off from its normal psychologic functioning corresponding to its past life and experience into something quite different so far as the consciousness or sense of identity of the individual is concerned. Recollections may be suppressed, new combinations of the highest association centers be brought into play and a complete break in the individual life be accomplished more or less completely or permanently. This is, perhaps, not an adequate explanation of the author's ideas, but it comes as near to it as is possible without going very much more extensively into their interpretation. The second part of the book, by Drs. Sidis and Goodhart, gives their observations of the case of the Rev. Mr. Hanna, which was carefully studied by them several years ago. It is an interesting account and probably the most thorough study of any such instance that has ever been made, but it does not seem to our mind to be altogether the best one to illustrate some of the phases of so-called multiple personality. The third part, by Dr. Sidis, is entitled "Consciousness and Multiple Personality," and goes at length into the pathologic psychology of the morbid conditions here discussed. The reader will find this part of the work interesting and suggestive in many ways, and the explanations given are, perhaps, as satisfactory as is possible with our present knowledge, but they do not appear to us to clear up the subject entirely. One can easily conceive of a subconscious personality under many normal conditions. Our common automatic movements naturally suggest it, and it may come more visibly into play under certain quasi pathologic conditions. The complete change of personality, however, many instances of which have been reported where the subject apparently takes up an entirely distinct and seemingly normal existence, is not so easily explainable. If we can exclude delusions, epileptic states which are themselves somewhat obscure and hysterical deception in these cases, there is left a rather difficult problem. The subject, however, is well studied in many of its aspects by the author and the work can be profitably pursued by anyone interested in such studies.

Practical Pediatrics. A Manual of the Medical and Surgical Diseases of Infancy and Childhood. By Dr. E. Graetzer, Editor of the *Centralblatt fur Kinderheilkunde* and the *Excerpta Medica*. Authorized Translation, with Numerous Additions and Notes, by Herman B. Sheffield, M.D., Instructor in Diseases of Children, and Attending Pediatrist (O.P.D.). Flexible Cloth. Pp. xii-544. Price. $3.00 net. Philadelphia. F. A. Davis Co.

The stated purpose of this volume is "to be brief and to the point, and contain as many parenthetical points as possible, so as to permit at a glance of the selection of the more important from the less important material." A book of this kind is usually justly subject to adverse comment because it recounts symptoms and remedies without discussing fundamental conditions and treatment principles; the result is a jumble of details difficult to assimilate and supplying no knowledge of relative values; accurate and complete, perhaps, but neither clear nor discriminating; really "practical," therefore, only in appearance. The present volume, however, is singularly free from the faults of its class. Of course, this book presupposes familiarity with disease in adults, and naturally it will not take the place of a thorough treatise on diseases of children. The section on the now very important subject of modification of cow's milk is notably unsatisfactory, but the chapter on palatable prescribing is valuable. With Dr. Sheffield's timely comments and addenda the book is generally up-to-date and extensive in its range.

Lehrbuch der Kinderkrankheiten für Arzte und Studireende von Dr. Adolf Baginsky, Professor der Kinderheilkunde an der Universität Berlin. Achte völlig neu durchgearbeitete und verbesserte Auflage. Paper. Pp. 1168. Leipzig. Verlag von S. Hirzel, 1905.

This classic on children's diseases appears in its eighth edition. Baginsky's book represents his own vast experience together with a painstaking study of the literature. The new edition follows very shortly on the seventh, indicating the large circulation which the book enjoys. Nearly every chapter gives evidence of alterations and additions. The subject matter is thoroughly reliable and altogether up to date. It would be difficult to select any subject which is not carefully and exhaustively considered. The subjects of diphtheria, typhoid fever, gastrointestinal diseases and the diseases of the new born are especially attractive. They contain the results of the author's extensive personal observations and clinical studies. The study of infant feeding is not treated in a dogmatic way, and the various plans of feeding which are in vogue in the different centers are discussed at some length. He advocates pure milk, properly diluted, whatever method be employed. The proprietary foods are mentioned and methods of administering them discussed, though their use is not advised.

Malformations of the Genital Organs of Woman. By Ch. Debierre, Professor of Anatomy in the Medical Faculty at Lille. With 85 Illustrations. Translated by J. Henry C. Simes, M.D., Emeritus Professor of Genito-Urinary and Venereal Diseases in the Philadelphia Polyclinic. Cloth. Pp. 182. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1905.

This work is of little practical use to the general practitioner and perhaps is not intended for him. The conditions it describes are not often met in practice. Many of the anomalies noted are of medicolegal importance, but the quotations from French non-medical writers might well have been omitted.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish *name or address* will be faithfully observed.

METHOD OF GIVING YEAST IN TUBERCULOSIS.

———, Aug. 15, 1905.

To the Editor:—Will you kindly enlighten me as to the proper way to administer yeast in the treatment of tuberculosis? Your review of article in the London *Lancet*, by W. R. Huggard, appearing in The Journal, July 1, 1905, says nothing about doses, time of administering, etc. If brewers' yeast is not accessible, could ordinary home-made yeast be used safely? J. W.

Answer.—It has not been definitely determined just what is the best way to administer yeast in the treatment of tuberculosis. Huggard and Morland have given the dried yeast suspended in milk or water, which may be drunk during the meal. Their doses have varied from three to ten grams (a piece the size of a filbert to that of a walnut) twice daily. A good variety of common pressed yeast may be used. The German *Presshefe* is preferred by some. More recently Huggard and Morland have been giving ten grams every five days as an experiment. This was suggested to them by the observation that the opsonic power of the blood (see Journal A. M. A., 1904, vol. 42, p. 1689) often falls somewhat immediately after the ingestion of yeast, but later rises above the normal level, and stays there for several days. They believe that the beneficial results of yeast are attributable to this rise in the opsonic power of the blood, which is a direct aid to phagocytosis. We would advise that too much dependence be not placed on the treatment till further evidence be produced regarding its true value.

State Boards of Registration

COMING EXAMINATIONS.

Wyoming State Board of Medical Examiners, State Capitol, Cheyenne, Wyo., September 6. Secretary, S. B. Miller, Laramie.

Massachusetts Board of Registration in Medicine, State House, Boston, September 12-13. Secretary, E. B. Harvey, Boston.

Michigan June Report.—Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports the examination held at Lansing, June 13, 1905. Sixty-eight candidates were examined, of whom 67 passed and 1 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
University of Michigan	(1905)	89.84, 88, 84.94, 91.10, 87.42, 88.52, 88.26, 78.31, 86.73, 91.47, 87.89, 88.57, 88.31, 87.52, 89, 87.57, 89.73, 87.36, 92.89, 86.52, 86.31, 85.73, 86, 88.42, 89.94, 83.47, 85.26, 86.42, 90.21, 85, 88.52, 90.36, 83, 84.05, 90.68, 86.52, 83.26, 86.36, 86.26, 82.10, 83.36, 89, 90.63
	(1904)	88.42, 83.94, 88.57, 85.10, 88.84, 87.47, 84
	(1903)	87
University of Michigan. Homeo. Dept.	(1905)	88.57, 83.78, 84.57
	(1903)	84.89
Woman's Med. Coll., Philadelphia	(1904)	91.89
College of P. & S., Chicago	(1898)	75.42
	(1896)	75.21
Kentucky School of Medicine	(1904)	85.10
Detroit Coll. of Med	(1905)	70.42, 80.26, 79
	(1902)	85.89
American Med. Miss. Coll.	(1901)	87.84, 83.94
Royal University of Turin, Italy	(1895)	84.57
New York Homeo. Med. Coll.	(1905)	86.21

FAILED.

College.	Year Grad.	Per Cent.
College of P. & S., Chicago	(1903)	66.31

The general average attained by representatives of the University of Michigan, excluding graduates of the homeopathic department was 87.1.

Ohio June Report.—In the report of the examinations held in June and published in The Journal, Aug. 19, 1905, the percentage of 88 attained by one graduate of the Western Reserve University was omitted. The general average attained by representatives of Cleveland College of Physicians and Surgeons was given as 82 when it should have been 89.14.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Aug. 19, 1905:

Rand, I. W., asst.-surgeon, granted leave of absence for one month, with permission to apply for an extension for one month.

Carter, Edward C., surgeon, leave of absence extended one month.

Heard, George P., asst.-surgeon, having reported arrival at San Francisco, Cal., from Manila, P. I., will take station at Army General Hospital, Presidio of San Francisco, Cal.

Glennan, James D., surgeon, and Darnall, C. R., asst.-surgeon, detailed members of examining board at Fort Monroe, Va.

Davidson, W. T., asst.-surgeon, relieved from duty at Army General Hospital, Presidio of San Francisco, and ordered to Presidio of Monterey, Cal., for temporary duty.

Gibner, Herbert C., and Bruns, Earl H., asst.-surgeons, relieved from duty with troops now on duty at the Sequoia and Yosemite National Parks, Cal., and to accompany Fifteenth Infantry to Philippine Islands. On arrival at Manila to report to commanding general, Philippines Division, for assignment to duty.

Cornman, Leighton R., contract surgeon, ordered from Army General Hospital, Presidio of San Francisco, to his home, Lowell, Mass., for annulment of contract.

Clayton, George R., contract surgeon, granted leave of absence for one month.

Lauderdale, C. E., dental surgeon, granted one month's leave of absence.

Stearns, Charles H., contract surgeon, returned from leave of absence to duty at Fort Monroe, Va.

Hallwood, J. B., contract surgeon, returned from leave of absence to duty at Fort Leavenworth, Kan.

Kieruluff, H. Newton, contract surgeon, relieved from further duty in the U. S. Transport Service, and ordered to duty in Philippine Islands.

Lemmon, Robert, contract surgeon, left Fort Preble, Maine, and arrived at Fort McKinley, Maine, for duty.

Wertenbaker, C. I., contract surgeon, left Madison Barracks, N. Y., en route to Ogdensburg, N. Y., with Third Battalion, Twenty-third Infantry.

Dougherty, J. C., contract surgeon, returned to duty at Fort Slocum, N. Y., from detached service at Fort Monroe, Va.

Byars, C. R., contract surgeon, returned to duty at Fort Sam Houston, Texas, from temporary duty at Fort McIntosh, Texas.

White, J. S., contract surgeon, left Fort Harrison, Mont., for his proper station, Fort Snelling, Minn.

Lowe, Thomas S., contract surgeon, will accompany Third Squadron, Thirteenth Cavalry, to Fort Sill, Okla., on completion of which duty will avail himself of leave of absence.

Navy Changes.

Change in the Medical Corps, U. S. Navy, for the week ending Aug. 19, 1905:

Brooks, F. H., asst.-surgeon, ordered to the Naval Hospital, New York.

Dunbar, A. W., surgeon, detached from the *Wyoming* and ordered home to wait orders.

Ames, H. E., medical inspector, detached from the Naval Academy and ordered to the *Maine*, for duty as fleet surgeon of the North Atlantic Fleet.

Lewis, D. O., medical inspector, detached from duty on the *Chicago* as fleet surgeon of the Pacific squadron and ordered home to wait orders.

Beyer, H. G., medical inspector, detached from the Naval Medical School, Washington, D. C., and ordered to special duty in connection with an international congress, Paris, France, and thence to the Asiatic fleet, for duty as fleet surgeon.

Dickson, S. H., medical inspector, detached from the *Maine* and from duty as fleet surgeon of the North Atlantic fleet, and ordered home to wait orders.

Biddle, C., surgeon, detached from duty as fleet surgeon of the Asiatic fleet, and ordered to the *Chicago* for duty as fleet surgeon of the Pacific squadron.

Berryhill, T. A., surgeon, ordered to Washington, D. C., September 1, for duty as instructor at the Naval Medical School, Washington, D. C.

Gatewood, J. D., surgeon, ordered to Washington, D. C., Aug. 22, 1905, for duty as instructor at the Naval Medical School.

Benton, F. L., P. A. surgeon, ordered to the Naval Hospital, New York, N. Y., for duty.

Murphy, J. A., P. A. surgeon., detached from the Naval Medical School, Washington, D. C., and ordered to the *Des Moines*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and noncommissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Aug. 16, 1905:

Sawtelle, H. W., surgeon, leave of absence granted him for one month from July 21, 1905, amended so as to be for twenty-three days.

Sawtelle, H. W., surgeon, to proceed to Norfolk and other points in state of Virginia for special temporary duty.

Cofer, L. E., P. A. surgeon, to proceed to Hile, T. H., for special temporary duty.

Lavinder, C. H., P. A. surgeon, to proceed from Gulfport, Miss., to New Orleans, La., and report to Surgeon J. H. White for special temporary duty.

von Ezdorf, R. H., P. A. surgeon, relieved from duty in the Canal Zone and directed to proceed to New Orleans, La., and report to Surgeon J. H. White for special temporary duty.

King, W. W., P. A. surgeon, to proceed to San Juan, Porto Rico, for special temporary duty.

Goldberger, Joseph, P. A. surgeon, to proceed from Mansfield to Alexandria, La., for [illegible]

Stimson, A. M., [illegible] letter of July 10, 1905, amended so a[illegible]sense for seventeen days instead of one month and fourteen days.

Ebert, H. G., asst.-surgeon. Department letter of July 13, 1905, granting him leave of absence for a period of two months from Aug. 4, 1905, revoked.

Addis, W. E., acting asst.-surgeon, to proceed to Jackson, Miss., and report to P. A. Surgeon G. B. Young for temporary duty.

Cleaves, F. H., acting asst.-surgeon, granted leave of absence for one day, Aug. 3, 1905.

Gray, R. H., acting asst.-surgeon. Department letter of June 24, 1905, amended so as to grant leave of absence for twenty-five days from July 6, instead of thirty days.

Houghton, M. W., acting asst.-surgeon, granted leave of absence for one day, Aug. 31, 1905.

Kennard, K. S., acting asst.-surgeon. Department letter of July 26, granting him leave of absence for a period of twenty-one days from Aug. 7, 1905, cancelled by Department letter of Aug. 11, 1905.

Nall, R. P., acting asst.-surgeon, to proceed to Jackson, Miss., and report to P. A. surgeon G. B. Young for temporary duty.

Stuart, A. F., acting asst.-surgeon. Department letter of May 27, 1905, amended so as to grant him leave of absence for twenty-eight days instead of thirty days, from July 3, 1905.

Holsendorf, B. E., pharmacist, to proceed to San Juan, Porto Rico, for special temporary duty.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended, Aug. 21, 1905:

SMALLPOX—UNITED STATES.

California: Los Angeles, July 22-August 8, 5 cases.
Florida: Jacksonville, July 22-August 5, 2 cases.
Illinois: Chicago, August 5-12, 6 cases; Danville, July 29-August 8, 1 case.
Indiana: South Bend, July 29-August 12, 2 cases.
Kentucky: Lexington, July 22-August 3, 3 cases.
Louisiana: New Orleans, July 29-August 12, 5 cases.
Massachusetts: Lowell, August 5-12, 3 cases.
Missouri: St. Joseph, July 22-29, 1 case.
New Hampshire: Nashua, July 23-August 12, 3 cases.
New York: New York, July 29-August 5, 3 cases, 1 death.
Ohio: Cincinnati, August 3-12, 5 cases.
Pennsylvania: August 5-12, Altoona, 1 case; York, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: June 3-10, 1 case.
Porto Rico: San Juan, June 1-30, present.

SMALLPOX—FOREIGN.

Brazil: Bahia, July 1-8, 1 death; Rio de Janeiro, July 2-9, 18 cases, 1 death.
Chili: Iquique, July 15-22, 1 case.
France: Paris, July 15-22, 32 cases, 2 deaths.
Great Britain: July 15-22, Birmingham, 3 cases; Bristol, 1 case; London, July 8-15, 2 cases; Manchester, July 15-22, 1 case; New Castle-on-Tyne, July 8-22, 5 cases; Nottingham, July 22-29, 1 case.
India: Calcutta, June 24-July 8, 7 deaths; Madras, July 1-7, 3 deaths.
Italy: Catania, July 21-27, 2 deaths.
Russia: Moscow, July 8-22, 7 cases, 9 deaths; Odessa, July 15-22, 3 cases.
Turkey: Constantinople, July 16-23, 3 deaths.

YELLOW FEVER—UNITED STATES.

Louisiana: Sellers, August 7, 4 cases; Shreveport, August 1-9, 2 cases; New Orleans, July 21-August 11, 720 cases, 118 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, July 2-10, 37 cases, 12 deaths.
Guatemala: Livingston, July 15-22, 2 deaths; Zacapa, August 3, 9 deaths.
Honduras: Choloma: July 26, 10 cases, 4 deaths; Puerto Cortez, July 1-24, 25 cases, 6 deaths; San Pedro, July 26, 100 cases, 19 deaths.
Mexico: July 30-August 5, Coatzacoalcos, 1 case; Vera Cruz, 4 cases, 1 death.
Panama: July 18-25, Colon, 6 cases, 2 deaths; Panama, 8 cases, 2 deaths.

CHOLERA.

India: Calcutta, June 18-July 8, 20 deaths.

PLAGUE—INSULAR.

Philippine Islands: June 3-10, Cebu, 4 cases, 3 deaths; Manila, 1 case, 1 death.

PLAGUE—FOREIGN.

Australia: Maruborough, June 10-17, 10 cases, 7 deaths.
Brazil: Rio de Janeiro, July 8-16, 2 cases.
India: General, June 18-24, 5,078 cases, 4,563 deaths; Calcutta, June 18-July 8, 56 deaths.

Medical Organization

Georgia.

Bartow County Medical Society.—This society has perfected its organization and has adopted the constitution and by-laws as component branch of the state association. Dr. Alfred T. Calhoun, Cartersville, is president, and Dr. Oliver H. Buford, secretary.

Clarke County Medical Society.—Physicians of the county met at Athens, June 28, and with the assistance of Dr. Samuel C. Benedict, Athens, councilor for the eighth district, organized a society on the standard plan and elected the following officers: Dr. James C. Bloomfield, president; Dr. Daniel D. Quillian, vice-president; Dr. Henry M. Fullilove, secretary-treasurer, and Drs. Isham H. Goss, Samuel H. Dillard and —Echols, censors, all of Athens, Ga.

Cobb County Medical Society.—This society was organized in Marietta the last week in July with ten charter members and the following officers: President, Dr. Charles T. Nolan, Marietta; vice-president, Dr. E. M. Bailey, Acworth; Dr. William C. Humphries, Acworth, secretary and treasurer, and Drs. J. G. Malone, William A. Kemp, Marietta, and J. E. Lester, Kennesaw, censors.

Jackson County Medical Society.—At a meeting called at Jefferson, August 9, by Dr. William B. Hardman, Harmony Grove, councilor for the ninth district, the physicians of the county organized a society on the standard plan with the following officers: Dr. J. C. Bennett, Jefferson, president; Dr. Leonard J. Sharp, Converse, vice-president; Dr. John A. Bryan, Pendergrass, secretary, and Dr. Albert D. White, Pendergrass, treasurer.

Illinois.

Boone County Medical Society.—Physicians of the county met in Belvidere, July 14, and organized a medical society with the following officers: President, Dr. Robert W. McInnes; vice-president, Dr. Daniel E. Foote; secretary, Dr. R. Boyd Andrews, and treasurer, Dr. John B. Leitzell, all of Belvidere.

Indian Territory.

Indian Territory Medical Association.—At a conference July 13 in Oklahoma City, between committees representing both the Oklahoma and Indian Territory medical associations, with a view to the union of the two organizations when statehood is secured, it was decided to hold a joint meeting at Oklahoma City, May 8, 1906. Dr. William E. Dicken, Oklahoma City, was chosen president, and Dr. LeRoy Long, South McAlester, I. T., secretary, of the joint session.

Kansas.

Cowley County Medical Society.—The physicians of Cowley County met at Winfield, July 13, and with the aid of Dr. Oliver J. Furst, Peabody, councilor for the fourth district, organized a society on the standard plan with a charter membership of 14. Dr. James W. Sparks, Arkansas City, was elected president; Dr. Leon Jacobus, Winfield, vice-president; Dr. Ernest F. Day, Arkansas City, secretary, and Dr. H. L. Snyder, Winfield, treasurer. A preliminary meeting was held June 24 in Winfield.

Kentucky.

Boone County Medical Society.—This society met at Burlington, July 23, and adopted a constitution and by-laws.

Madison County Medical Society.—At the meeting of this society in Richmond, July 22, Dr. Frank H. Clarke, Lexington, president of the Kentucky State Medical Society, and Dr. Isaac A. Shirley, Winchester, made addresses on "Medical Organization."

Missouri.

Worth County Medical Society.—On July 12 Dr. E. H. Miller, councilor of the third district, met the physicians of the county at Grant City and assisted in the organization of a county society on the standard plan. Dr. Oliver P. M. Mills, Grant City, was elected president; Dr. E. Paulus Nesbitt, Sheridan, vice-president; Dr. J. K. Phipps, Grant City, secretary, and Dr. J. F. Bove, Allendale, treasurer.

Pennsylvania.

Clinton County Medical Society.—At the meeting held July 21, at Lock Haven, the committee appointed at the last meeting to submit a report on the matters outlined in Dr. McCormack's address, reported, recommending a uniform fee bill; the adoption of some system of delinquents throughout the county; minimum fee for examining applicants for life insurance; a definite understanding about night calls, and fee for same; the holding of clinics at the hospital at each meeting of the society; a definite understanding as to what constitutes contract practice and rules governing the same; that all professional positions shall be paid according to regular fee bill rate, and the adoption of a resolution instructing the delegates to the state convention to concur in any movement tending to the unification of the profession in the state. The report was adopted and a committee consisting of Drs. Francis [illegible]ll, Lock Haven; C. L. Fulmer, Renovo, and Saylor J. McGhee, Mill Hall, was appointed to carry out the recommendations.

South Carolina.

Florence County Medical Society.—This society, at its meeting in Florence, July 10, elected Dr. N. W. Hicks, Florence, president, and adopted the by-laws suggested for county societies by the American Medical Association.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Administration of Digitalis.

A Hecht, in *Amer. Jour. Med. Sciences*, states that in the treatment of diseases of the heart it is necessary not only to strengthen the heart muscles, but to keep up the patient's nutrition. For this reason drugs that tend to upset the patient's digestion must be avoided. In this connection he mentions digitalis as a preparation which is especially liable to disturb the stomach when it is in an atonic condition, as this drug is likely to remain in the stomach for a considerable length of time and to produce nausea. On this account he recommends that it be prescribed with agents which tend to counteract this tendency. The author recommends the following formula:

℞.	Pulv. digitalis			
	Quin. hydrochlor., āā	gr. xx	1	30
	Ext. nucis vom	gr. iv-vii		25-.45

M. Ft. capsulæ No. xxx. Sig.: One capsule three times a day.

H. O. Hall, in *Amer. Medicine*, calls attention to the fact that digitalis may cause delirium and hallucinations which are sometimes attributed to the disease affecting the patient instead of to the digitalis. He, therefore, states that in all cases in which delirium occurs in patients suffering from heart diseases, it should be decided that the toxic effect of digitalis is not a factor in the production of these symptoms. This can be done by attention to the elimination, as digitalis is cumulative in action.

In cases of cardiac dropsy the following combination is recommended by Beasley:

℞.	Infusi digitalis	ʒi	4	
	Potass. acetatis	gr. x		65
	Tinct. opii	m. v		30
	Aquæ chloroformi q. s. ad	℥ss	15	

M. Sig.: To be taken at one dose and repeated three times daily.

For nervous palpitation he recommends the following:

℞.	Tinct. digitalis	m. v		30
	Syr. aurantii	ʒi	4	
	Acidi hydrocyanici dil	m. ii		12
	Aquæ camphoræ q. s. ad	℥i	30	

M. Sig.: At one dose and repeat once in four hours if necessary.

A combination of digitalis, scilla and hydrargyrum, for the treatment of cardiac insufficiency, accompanied by edema and dropsy, is as follows:

℞.	*Pulv. digitalis*			
	Pulv. scillæ			
	Pil. hydrarg., āā	gr. i		06
	Ext. hyoscyami	gr. ii		12

M. Ft. pillula No. i. Sig.: One such pill twice daily.

The following combination is sometimes of value in heart cases:

℞.	Tinct. digitalis	m. x		65
	Spts. chloroformi	m. xv	1	
	Inf. gentianæ co. q. s. ad	℥i	30	

M. Sig.: At one dose and repeat three times daily. Or:

℞.	Tinct. digitalis	m. v		30
	Spts. glycerylis nitratis (1 per cent.)	m. i		06
	Tinct. strophanthi	m. iii		20
	Caffeinæ citratæ	gr. i		06
	Spts. arom. q. s. ad	ʒi	4	

M. Sig.: At one dose in a wineglass of water and repeat two or three times a day.

Lobar Pneumonia in Children.

Lobar pneumonia in infants, according to Koplik, in *Boston Med. and Surg. Jour.*, differs in children as compared to adults in that double pneumonia is less frequent in children and pneumonia of the upper lobes is more frequent. The treatment should be outlined in much the same manner as in other infectious diseases or in typhoid fever.

The temperature requires treatment according to the mischief it is doing. Some infants bear high temperature remarkably well, while others do not. Hydrotherapy is the sheet anchor in the treatment of temperature. And in its application it must be kept in mind that the Brand bath or the cold bath are second in importance to the milder measures of sponging or to the application of cold compresses wrung out of water at a temperature of from 75 to 80 F. Infants, as a rule, bear the cold bath very badly and when the reaction is delayed it is difficult, particularly in bottle-fed infants, to rouse them out of the depression caused by it. The author applies a definite index for hydrotherapy in these cases. If a child does not react from a cold sponge, a lukewarm sponge is applied, and in some infants it is impossible to sponge at all. In such cases he recommends compresses, wrung out of water at a temperature of from 75 to 80 F. and applied from the neck to the umbilicus.

The heart should always be supported if necessary. Children above 5 years of age require but little support for the heart, as a rule, while those under 5 frequently require active support.

Alcohol and digitalis are the best remedies in supporting the heart in lobar pneumonia in infants, using a reliable tincture of digitalis and alcohol in the form of whisky, which is much preferable, in the author's opinion, to brandy, and it should not be given in too large doses on account of the danger of upsetting the stomach. If cyanosis be present, showing the strain on the right ventricle, nitroglycerin is regarded as the most useful remedy, given in doses ranging from 1/100 to 1/150 grain (.0006-.0004) every few hours. In younger children a smaller dose is required. He pleads for greater caution in the use of strychnia in pneumonia on account of the dangers from strychnia poison and also because of the lack of knowledge as to its exact action. It should not be used in nervous children who, without its use, show tremors and unrest due to toxemia and high temperature. The nutrition of the patient is by far the most important thing to be considered in this disease. Water should be given frequently, if the tongue is dry, in teaspoonful doses, perhaps every half-hour, if it does not disturb the child too much. The hourly system of stimulation is to be condemned. The medicines and food should be given at about the same time if it can be so arranged, so as to disturb the patient as little as possible. If these intervals can be lengthened to every three hours so much the better for the patient, for rest is an important element.

[In bottle-fed infants and in young children it is often unwise to give food and medicine at the same time, as dislike for the medicine may cause the child to refuse to take the necessary nourishment.]

He has not seen much benefit from the use of oxygen. The room should be kept at a temperature of from 67 to 68 F. and well ventilated; it should be quiet and isolated.

Complications must be watched for. If during the course of the disease a high temperature reigns (105° F.) for any length of time, the ears of the patient must be examined, and if the temperature does not drop at the end of seven or eight days, the chest should be examined for effusion, and if that is absent, examine the heart carefully. The cough should be controlled and, if necessary, codein may be used, or paregoric or the wine of opium, rarely morphin or the stronger preparations of opium. In younger children tympanitis is troublesome and for its relief a calomel purge is of service.

Tympanitis embarrasses the heart (and by some authorities produces atelectasis of the lungs) and calomel relieves the condition when given in five-grain (.30) doses for a young child. Ordinarily, one-half grain doses (.03) repeated every two hours will suffice.

[A warm mustard bath will often aid in giving relief when tympanites is present, especially if the bath be preceded by a colon flushing with warm water.]

Collapse is treated by warmth to the body and the internal administration of camphor and nitroglycerin.

Conjunctivitis.

In the treatment of chronic catarrhal conjunctivitis, the *Internat. Jour. of Surgery* recommends removal of the cause, the use of glasses to remove the eyestrain. Lachrymal and nasal troubles should be corrected. If atmospheric conditions are the cause a change of climate is recommended. Sometimes the occupation by working in irritating vapors produces this condition. After the cause has been removed the conjunctiva becomes normal, as a rule. In some cases a stimulating astringent is necessary. For this purpose the following combination is recommended:

℞. Zinci sulphatis........................gr. i |06
Aquæ dest ....℥i 30|

M. Sig.: A few drops to be instilled into the eye. Or:

℞. Acidi borici........................gr. xv 1|
Aquæ dest ....℥i 30|

M. Sig.: Use as an eye lotion. Or:

℞. Acidi tannici........................gr. x |65
Glycerini ....℥i 30|

M. Sig.: To be applied locally to the conjunctiva. Or:

℞. Argenti nitratis....................gr. ss |03
Aquæ dest ....℥i 30|

M. Sig.: Apply locally with an applicator.

Other astringents such as copper sulphate or alum may be lightly applied to the everted lid every other day. Ointments of mercury are also of service as follows:

℞. Ung. hydrarg. oxidi flavi.............gr. i |06
Lanolini ....ʒi 4|

M. Ft. unguentum. Sig.: A small piece applied locally to the conjunctiva and light massage given to the closed lid. Or:

℞. Ung. hydrarg. ammon...............gr. i |06
Lanolini ....ʒi 4|

M. Ft. unguentum. Sig.: A small amount to be applied locally.

It is often necessary in these cases to change from one remedy to another in order to obtain the best results. In cases of follicular conjunctivitis the general health and hygienic surroundings of the patient should be inquired into and the patient should, in a way, be quarantined, having a separate bed, bed linen, towels, etc. Internally, iron in some form is of value and locally the astringents used in the chronic catarrhal form are of service. The follicle may be destroyed by expression with the thumb nail or dressing forceps.

Psoriasis.

Shoemaker recommends the following *application locally* in the treatment of psoriasis:

℞. Acidi salicylici
Sulphuris *sublim.*, āā..................ʒi 4|
Olei eucalypti ....ʒss 2|
Ung. aquæ rosæ ....℥i 30|

M. Ft. unguentum. Sig.: Rub a small amount in well on the patches.

Internally, he recommends:

℞. Creosoti ....m. ii |12
Pepsini (scale) ....gr. ii |12

M. Ft. capsulæ No. i. Sig.: One capsule three times a day, after meals.

He also recommends chrysarobin in the treatment of psoriasis, combined as follows:

℞. Olei *cadini* ....ʒss 2|
Chrysarobini ....gr. xx 1|30
Ung. zinci oxidi ....℥i 30|

M. Ft. unguentum. Sig.: Apply locally to the affected areas.

Erysipelas.

In order to prevent the infection from spreading, Floeckinger, in *Amer. Therapist*, recommends that the border line be painted with pure tincture of iodin. If the point of origin can be located he cauterizes it with pure carbolic acid. He recommends the tinctura ferri chloridi in doses of from 10 to 20 (.65-1.30) minims in glycerin every two or three hours. He also recommends the use of antistreptococcic serum as an injection in doses of 20 c.c., and he repeats the dose in from six to twelve hours, according to the severity of the infection. He regards this line of treatment as the most effective. Abscess formation demands multiple incision.

The *Med. Press* recommends the following combinations in the treatment of erysipelas:

℞.	Guaiacol		
	Tinct. iodi		
	Spts. etheris, āā	ʒi	4

Conclusions Based on Narrations of Patient.—The Supreme Court of Illinois says, in Stevens vs. People, that, while it is competent to show exclamations indicating pain as being some evidence of pain itself, and to show where the patient locates the seat of his or her suffering, this court knows of no well considered case where it is held competent for the physician to testify that he reached his conclusion or formed his opinion as to the ailment or physical condition of the patient from the cause or history of the injury, ailment or disease as narrated by the patient.

Railroad Company Not Liable for Negligence at Hospital.—The Court of Appeals of Kentucky says, in Illinois Central Railroad Company vs. Buchanan, that the latter party while in the service of the railroad company had his kneecap broken and was sent to the Illinois Central Hospital for treatment. He subsequently brought this action against the railroad company for damages, claiming that while under the care of the physicians and nurses of the hospital he was unskillfully and improperly treated. It was shown, however, that the Illinois Central Hospital Association, which conducted the hospital, was a separate and distinct corporation from the railroad company, although all officers and employes of the railroad company were made members of the corporation, with certain exceptions, and sums which the members were required to pay were collected by the railroad company to pay the expenses of the hospital, and went into the hands of the treasurer of the hospital association, who was also the treasurer of the railroad company. So the court says that the proposition was presented that, because the railroad company simply acted as the agent in the gathering of the funds from its employes for the hospital purposes, it thereby made a contract to be responsible for the conduct of those in control of the hospital. The conclusion reached by the court is that the railroad company was in no way liable for the conduct of the directors of the hospital corporation, or the physicians or the attendants at the hospital. The court says that if the railroad company was the real party at interest, and was simply using the hospital association for its financial profit, then the court might consider whether or not it was a case where it should look at the substance, and not the shadow, of things, in determining its liability. Doubtless the railroad company was indirectly benefited by its employes having proper and humane treatment at the hospital prepared for them, but that incidental benefit could not raise the question suggested, nor make it liable for the act of servant or agent of an independent corporation.

Status Lymphaticus Death During Chloroform.—The Second Appellate Division of the Supreme Court of New York says that the trial judge told the jury in the malpractice case of Wood vs. Wyeth that in a civil case the evidence to establish negligence must be just as strong as that required to establish guilt in a prosecution for manslaughter. No discussion is necessary to show that such is not the law. It is conclusively settled by authority in the state of New York that in a civil case the plaintiff rests only under the burden of proving his case by a preponderance of evidence, and not beyond a reasonable doubt. The law required that the physician, on undertaking treatment of the patient, should possess that reasonable degree of learning and skill ordinarily belonging to a physician and surgeon in the locality in which he practiced, and imposed on him the duty to use reasonable care and diligence in the exercise of his skill and the application of his learning, and to act according to his best judgment. It was conceded on the trial that there was no question as to the physician's learning or skill, so that the only remaining questions were whether he used reasonable care and diligence in the exercise of his skill and the application of his learning to accomplish the purpose for which he was employed, and whether he acted according to his best judgment. If he did, he was not legally responsible for the death of the boy. According to the physician, he found the patient suffering from blood poisoning, which was in danger of becoming general. His temperature was more than 100 degrees, and he knew positively that blood poisoning was going to get into his system. He thereon resolved to operate on the boy that day, to try to save him from this general blood poisoning. He then questioned the patient as to whether he had had any breakfast, and the boy responded that he had had a piece of meat and some bread. He used chloroform as an anesthetic instead of some other agent because he believed it was safe and better for the child, who presented such a bad appearance that the physician did not intrust anybody else to administer the chloroform, but gave it himself. Unfortunately, the chloroform proved fatal, because of a condition of the patient's system described as "status lymphaticus," not discoverable by any physical examination that could have been made before death. The theory of the plaintiff's counsel, as indicated by a question to the witness, was that the boy had eaten a breakfast consisting of a quarter of a pound of pork, a quarter of a pound of ham, four slices of bread, two eggs, and a cup of coffee, only three hours before the operation; but, if this were the fact, there was no evidence, the court says, that the physician was informed of it. The test here applicable to his conduct was not what the patient had actually done in the way of taking food, but what the patient told the physician on that subject. The case, instead of being one of negligence, appeared to be only another melancholy instance of a death on the operating table in a charity hospital of a patient being treated with a high degree of skill and care by a surgeon of unquestioned learning. Such a death is always painful enough to the conscientious surgeon under whose care it occurs, but it can not subject him to any legal liability, where there is no sufficient proof that he was derelict in the performance of his professional duty toward his patient.

Admissibility of Dying Declarations.—The Supreme Court of Illinois says, in Brom vs. People, that the admission of the dying declaration of the deceased in a homicide case forms an exception or qualification to the well-settled rule that secondary or hearsay evidence is not admissible. The reasons usually given in the books for the admission of such declarations are, first, that the solemnity of the occasion under which they are made dispenses with the necessity of an oath; and, secondly, the impossibility in many cases of producing better proof of the homicide makes it necessary that such declarations be admitted in order that those clearly guilty may not escape punishment. Such declarations are made not under oath. There is no opportunity given to cross-examine the party making the same, and the accused is deprived of the right to meet his accuser before the court and jury face to face, and the courts for those reasons are not disposed to extend the rule to embrace cases which do not clearly fall within all its limitations. The cases in which said declarations are admitted have been confined by the courts to cases where the declarations were made by the injured party under the fixed belief and moral conviction that his death was impending and certain to follow almost immediately. The declarant in this case may have been excited from what the physicians told him, and may have thought, from his condition, that he would not get well, and that he might eventually die from the effects of his wounds. That, however, was not sufficient to make the declaration admissible. He must have entertained at the time he signed the declaration a fixed belief and moral conviction that his death was then impending, and certain to follow almost immediately. The question of his belief that his death was impending and certain to follow almost immediately could not alone be determined from what the physician testified he said on that subject on the occasion of signing the instrument, but his acts were to be considered in connection with his words, as well as the circumstances which surrounded him at the time the declaration was signed, in determining what his belief relative to his immediate death was at that time. Furthermore, while the court does not hold that he could not have ratified a statement prepared the previous evening by the state's attorney, so as to have made it his dying declaration, the evidence that he did ratify it after he was impressed with impending death should be of such a character as to satisfy the mind of such ratification beyond any reasonable doubt.

Operation to Improve Appearance After Injury.—The Supreme Court of Oregon says that in the personal injury case of Busch vs. Robinson, where the plaintiff's hand was caught between the rollers of a mangle, a physician, after describing the extent of the injury, and that there was a webbing of the fingers down to the middle joint, testified that the cosmetic effect of the hand would be improved by an operation dividing the fingers again so that the woman could wear a glove; that, while it would probably not improve the usefulness of the hand, it would much improve its appearance; and that the reasonable charges of a surgeon for performing the operation would be about $100. He further testified, over objection, that it would be better for the plaintiff to go to a hospital during the operation and treatment, and that the expense there would be $2 a day for about thirty days. The objection to this testimony was that the expense attending the further treatment of the hand to improve its appearance was not a proper element of damages for the jury's consideration. But the court says that it would seem that the operation or further treatment and the expense attending it would be but the natural and probable result of the injury—as much so, almost, as it was necessary to employ a surgeon in the first instance to secure proper treatment for saving the hand, if possible. It was, therefore, within the rule for the measure of damages.

5 *Anastomosis and Transplantation of Blood Vessels. A. Carrel, Chicago.
6 *Mercuric Chlorid, Intravenously or Intramuscularly, for Epidemic Cerebrospinal Meningitis. R. Hogner, Boston.

1. **Conditions Determining Variations in Energy of Tumor Growths.**—Loeb asserts the rate of tumor growth is not only influenced by the species into which the tumor is transplanted, but also by variations which exist among individuals or families of the same species. Under certain conditions a state of active immunity can be experimentally produced. It can be accomplished more easily with some tumors than with others. The energy of tumor growth can be experimentally increased through successive transplantations up to a certain maximum. It is also possible to cause an experimental decrease in the energy of tumor growth. These variations are caused by a direct stimulating or depressing effect on the tumor cells. Contact metastases may occur, and different tumors which are morphologically similar or identical behave differently in this respect. The greatest care ought to be exercised to prevent a tumor from touching the wound during extirpation. The fact that surgeons operating on tumors do not become infected agrees with the facts found in experimental tumor inoculations. Tumor growth is primarily due to an increased energy of growth of those cells from which the tumor takes its origin; it can not be due to a lowered resistance of the organism in which the cells carry on their apparently unlimited growth. If a tumor can not be successfully inoculated into other animals, it is probably not due to the fact that other animals are more resistant toward the growth of inoculated tumor cells than the animal in which the tumor growth developed originally, but to other causes still unknown.

2.—See abstract in The Journal, May 27, 1905, page 1707.

3. **Diseases of Heart and Their Treatment.**—Lerch emphasizes the fact that health and life depend largely on the equilibrium that exists between arterial and venous pressure. As long as compensation is perfect, no matter what the lesion may be, the patient does not suffer any inconvenience. The object, therefore, of all treatment must be to keep such a compensation or to re-establish it when lost. In patients with a completely broken compensation rest and drugs must be used. As soon as the compensation is re-established mechanical and dietetic treatment must take the place of drugs, and if under its employment the heart again begins to fail, the prognosis is grave.

5. **Anastomosis and Transplantation of Blood Vessels.**—Carrel states that when a segment of artery is removed the circulation may be restored in the peripheral portion by interposing between the cut ends a segment of vein. Experiments on dogs were undertaken with the view of finding a new treatment of aneurism. A segment of carotid or femoral artery was resected. The continuity of the vessel was restored by interposing a segment of jugular or femoral vein. After completion of anastomosis, the peripheral arterial circulation was immediately restored. The anastomosis and the venous wall adequately support the arterial blood pressure. The circulation below the venous segment appears normal.

6. **Mercuric Chlorid in Epidemic Cerebrospinal Meningitis.**—Hogner has found intragluteal injections of mercuric chlorid, twice a day, of great value in the treatment of epidemic cerebrospinal meningitis. He uses: Mercuric chlorid, 2 parts; sodium chlorid, 9 parts; distilled water to 1,000. One to 4 c.c. are used for intravenous or intramuscular injection, once or twice a day. The maximum dose intravenously is 4 c.c. of the solution. Hogner prefers the intravenous injections and he cautions against extravenous injections on account of the bad local effects.

7 *New Method of Orchidopexy. C. Beck, New York.
8 **Dynamics of Dreams.* A. E. Gibson, Los Angeles, Cal.
9 *Length of Enteron (Small Intestine). B. Robinson, Chicago.
10 Position of the Bladder in Fibroid of the Uterus. J. A. Schmitt, New York.
11 Dual Genital and Extragenital Chancres—Chancre a Distance. M. L. Heidingsfeld, Cincinnati, Ohio.

7. **New Method of Orchidopexy.**—Beck says that the widespread opinion that a retained testicle will descend *from the* inguinal canal to the scrotum at the age of puberty is erroneous, and that while it may sometimes occur, he has never seen it do so himself. He, therefore, thinks *it* unwise to defer surgical action until puberty, owing to the risk of atrophy, and advises operation after the third year, unless there is some contraindication. His method of operating, which he calls the "necktie operation," is essentially as follows: The incision is like the *Bassini incision*, prolonged downward, and the testicle is lifted from its bed and freed from all adhesions. It is then pulled down into a pocket prepared for it in the scrotum. In order to secure it there, a flap is dissected from the outer margin of the inguinal ring downward, and turned in such a manner that it can be attached to the opposite layer in a semilunar shape. Thus this band surrounds the testicle

like a necktie, the testicle being retained as in a buttonhole. The length of the semilunar flap will be dictated by the greater or lesser extensibility of the cord. The aponeurosis is then united above.

8. **Dynamics of Dreams.**—Gibson presents an exhaustive analysis of the physical and psychical basis of dreams and sums up his views in part as follows: Dream and waking differ in degree and form of manifestation only, not in principle and essence. Like waking consciousness, dream reveals, but does not create. The same world that surrounds the waking individual surrounds the dreamer, only the viewpoints and media of observation are changed. As the life experience of an individual in his waking consciousness receives its character and value by and through his power of response to environment, so in a similar way the value of a dream depends on the power of the ego to respond to consciousness in its various forms of emotions, ideas and feelings which constitute the environments of the subjective or dream plane. Waking or dreaming, the individual is, or becomes, what he chooses to be at any given moment of his existence. The background for ordinary dreams consists of undigested remnants of waking life. Hence, ordinary dreams are merely undigested life, being made up by longings, desires, anticipations, idle hopes and miscarried realizations, which, occupying the mind during the day, are overtaken by sleep before having reached their fruition. Hence the mixture, in most dreams, of the sane and the insane, of truth and delusion. On the other hand, the life lived out and assimilated in a purposeful existence becomes absorbed in the formation of character and leaves no residue to form the bizarre staging for the confused dream. And to such an individual the intuitions of dream life, with their dazzling imagery, will introduce symbols, which, properly interpreted, may carry the significance of prevision or prophecy. Therefore, to turn dreams into useful, intelligent and intelligible factors, we must fill our waking life with deeds and thoughts of universal usefulness, and freight the train of events with an unflinching devotion to duty and virtue.

9. **Length of Enteron.**—Robinson reports the results of measurements made at autopsies on 450 males and 150 females. The average length of the enteron in the males was 23 feet, and in the females was 19 feet. The length of the enteron may be very much modified by local or general disease, especially during childhood, and also by the character of the food consumed. The enteron increases in length most rapidly a few months subsequent to birth, when it may grow one and one-half feet a month, and it assumes its chief length in early childhood. A subject with a maximum length of enteron possesses a stronger constitution than a subject with minimum length, as he can digest and economize more food. The human enteron presents colossal differences as to length (males 11½ feet minimum, 32 feet maximum = 20 feet, and female, 10½ feet minimum, 30 feet maximum = 19½ feet). This variation of 20 feet is almost equal to the length of an average enteron. The enteron varies over double to two and one-half times its length. In adults the relation of the length of the enteron to the body length is as 7.2 to 1. There is a vast difference between the absolute and relative length of the enteron in man. The enteron measured *in situ* is 3 to 6 feet less in length than when extirpated. Different diseases of the enteron may result in elongation or contraction.

16 Malarial [illegible] Fla.
17 The Docto [illegible] Ga.
18 Case of C [illegible] with Hydrom [illegible] ago.

12. **Analytical Study of Ectopic Pregnancy.**—A clinical study of 30 cases leads Brickner to draw the following conclusions: Sterility does not necessarily precede the development of ectopic pregnancy. If it does exist, its cause is often the same as the cause of abnormal pregnancy. The main characteristic of the bleeding in ectopic gestation is its great irregularity, there being no type. As a general rule it is not profuse. It may be constant or intermittent, and its character or profuseness has no relation to the type of the lesion. A chilly feeling often accompanies the bleeding, and vomiting and nausea often accompany the first flow. The uterine flow has apparently no connection with the death of the fetus. The pain in tubal pregnancy is usually localized over the side of the lesion. It has no definite character; it may be cramplike over the affected tube; it may simulate labor pains; it may be sharp and sudden, or it may be of a bearing-down nature. The pain during a tubal abortion and that concomitant with the presence of a hematosalpinx is usually cramplike. The usual symptoms of pregnancy may be present. They are frequently absent, but their absence does not militate against the possibility or probability of an ectopic pregnancy. Tenderness on palpation of the mass adjacent to the uterus is of great diagnostic value when taken in connection with the history and the other pelvic findings. A rise of temperature between 99 and 100 F., in the absence of signs of infection, is worthy of consideration in the diagnosis. The causative factors of tubal pregnancy are probably numerous. Not one element, but many, may bring about the condition in different instances. It is likely that atavistic tendencies, congenital or acquired anomalies, pelvic inflammations, ovarian and tubal disease, all play a rôle in individual cases; but none of these factors alone is sufficient to explain all cases. There are as yet no definite data by which we can differentiate diagnostically between all the varieties of ectopic gestation. Occasionally this may be done, but it is impossible always to distinguish between an unruptured tube and a tubal mole. A hematocele and a freshly ruptured tube can almost always be differentiated from the other usual lesions.

13. **Treatment of Chronic Nasal Catarrh.**—In treating the several forms of chronic nasal catarrh it is Kolipinski's custom to have the patients seated with head erect and the mouth open. The anterior nasal cavity is exposed with a speculum, the tip of the nose elevated and the sulphur freely and thoroughly blown in with a strong powder blower. This has been properly done when the powder appears from mouth and opposite nostril and an irritative cough results. The treatment is repeated on the other side. The posterior nasal space and naso pharynx may also be treated directly by way of the floor of the nose or fauces. These procedures are not entrusted to the patient unless he is unusually attentive to his own case. They are made two or three times a week for a month, and once a week for the next two months. The local sensations of sulphur are not unpleasant. Occasionally in women it sets up a conjunctival hyperemia when used too profusely or when accidentally blown on the face, and some women complain of nasal irritation and pain; then it is best to use the treatment but once a week. The cases must be selected carefully, those in which there is no other primary nasal disease, deflection, deformity or growth must be treated surgically. This method of treatment has proved of value in simple, chronic, hypertrophic, atrophic and phlegmonous *rhinitis; and in simple chronic and hyperplastic nasopharyngitis.*

24 *Unusual Sequel to Kraske's Operation. C. B. Kelsey, New York.
25 Six Lectures on the Diseases of the Blood. J. M. Swan, Philadelphia.

21. **Abdominal Pain.**—Babler urges that every effort be made to ascertain the true cause of any sudden, severe, persistent pain in the abdomen, and cautions against the use of morphin for the purpose of allaying the pain. A complete history of the patient must be secured and a careful examination made. Ascertaining the site of the initial pain is of more diagnostic value than the location of the diffuse pain. Such pain is of grave import and demands immediate investigation.

24. **Unusual Sequel to Kraske's Operation.**—Two years after the operation Kelsey's patient noticed a tumor over the sacrum which gradually increased in size. On examination this tumor proved to be a hernia escaping behind the rectum through the opening into the pelvis made by the old incision.

30 *Scopolamin-Morphin as an Adjuvant in the Administration of General Anesthesia. M. G. Seelig, St. Louis.

30. **Scopolamin-Morphin as Adjuvant to General Anesthesia.**—The purpose of Seelig's paper is to present a series of 65 general anesthesia administrations, showing that the method used is one that merits recommendation and trial. This series included the following range of cases: Abdominal hysterectomy, 8; vaginal hysterectomy, 6; hernia, 5; plastic operations, 8; operations on the tubes and ovaries, 11; uterine fixations, 6; curettements, 6; hemorrhoids, 3; fistula in ano, 2; thyroidectomy, craniectomy, orchidectomy, appendicectomy, costectomy, nephropexy, tumor of breast, cyst of neck, pelvic abscess, exploratory laparotomy, one each. In every instance the patient received a hypodermic injection of scopolamin hydrobromid, grain 1/100, and morphin, grain 1/6, one half-hour before the administration of the general anesthetic. The general anesthesia was induced by means of the ethyl chlorid-ether sequence administered through the Bennett inhaler. Of these 65 patients only one vomited or retched while on the operating table. Seventy-seven per cent. of the patients did not vomit at all. One-third of the patients that did vomit, vomited only once, and then only from two drams to one ounce of clear mucus. Nausea was never pronounced except in two cases, and vomiting never occurred earlier than two hours after the operation. The advantages of this method are: Lessened amount of anesthetic necessary, absence of salivation, avoidance of the stage of excitement, marked reduction in the liability to vomit, and quiet and freedom from pain after operation.

37. **Hyoscin Hydrobromate for Morphin Habit.**—Bering advises placing the morphin habitué in a sanitarium where he can be under constant supervision and at the same time is removed from the sympathetic influence of friends. The room should be darkened and should contain as little furniture as possible. The patient must not be left alone a moment during the administration of the hyoscin, nor for the first twenty-four hours after the last dose of hyoscin has been given. The night before beginning treatment a vapor bath is given to secure free action of the skin. Bering also endeavors to secure free elimination of all toxic material from the system, using for this purpose strychnin sulphate in doses ranging from 1/32 to 1/8 grain every two hours, for three or four doses, with calomel, podophyllum, ipecac, etc. Hyoscin is then given in doses ranging from 1/100 grain every hour to 1/400 grain every four hours, until the full physiologic action is secured. From that time on just enough hyoscin should be given to continue this action for a period ranging from thirty to forty hours, when the hyoscin is discontinued, if the patient is free from pain and desire for the drug. If not, the hyoscin is resumed for another twelve or twenty-four hours. If the patient goes to sleep during the administration of the hyoscin no more is given until he awakens. Should the patient at any time show signs of pain, more hyoscin must be given. The action of hyoscin is not the same in any two patients. While it is perfectly safe if used carefully, it is a powerful agent for harm when not so used. Each patient must be closely watched. If a cardiac stimulant is required, Bering gives spartein sulphate in 1/8 to 1/4 grain doses, repeating the dose every four to six hours, as indicated.

61 Cysts of the Pancreas. R. P. McReynolds, Philadelphia.
62 General Practitioner as a Temporary Ophthalmologist. C. P. Franklin, Philadelphia.

57. ***Aneurism* Treated by Wiring and Electrolysis.**—The first case reported by Hare is that of a woman of 50 suffering from an aneurism involving the superior and posterior portions of the transverse arch of the aorta, including the origin of the large vessels. Gold wire to the amount of eight feet was passed into the sac through an ordinary insulated needle, and the electric current started at 5 milliamperes and gradually increased to 50 milliamperes, was passed through the sac for thirty minutes. Before the operation was completed the patient was relieved of pressure symptoms to some extent, and for several weeks afterward was able to sleep in a reclining posture with perfect comfort. Six months after the operation the growth which had been formed by the operation at the

margin of the clot began to enlarge and death finally occurred, the result of pressure on the trachea combined with exhaustion. At the autopsy the wire was found imbedded in a clot. The second case reported was that of a man who presented a mass which filled the epiclavicular space at the right side near the sternum and passed backward under the sternomastoid muscle. Two feet of gold wire were introduced into the tumor, which proved to be an aneurism, and electrolysis was used, as in the first case, for forty minutes. Two weeks after the operation the area into which the wire had been introduced was firm and devoid of expansile pulsation. Death took place two months later, the result of exhaustion and interference with respiration and deglutition. The aneurism took its origin from the inferior portion of the wall of the innominate artery. The sac was lined with a laminated clot, the interior of which was occupied by a black, rather thick liquid. No trace of the wire could be found in any part of the clot. In the third case, one of aneurism of the thoracic aorta just below its descending portion, nine feet of wire were introduced and the electric current was passed for about three-quarters of an hour. The patient lived four months, dying at the end of that time from pressure and exhaustion. The autopsy revealed an enormous laminated clot filling the entire sac, with the wire coiled in the center of the aneurism, embedded in fibrin, through which the blood had formed a channel. Hare says that it is noteworthy that practically in all these cases the operation was followed by immediate relief of the pressure symptoms, and a diminution in the expansile pulsation of the part operated on. The degree of relief varied very considerably, but all the patients experienced some benefit. Several of them volunteered the information that they felt amply repaid for the operation by the relief which they obtained. In each instance the ultimate death of the patient in no way proved that the operation was at fault. It indicated only that the disease in the blood vessel wall was so extensive that the point of greatest weakness having been reinforced, the vessel then gave way at the margin of the clot, and at a place where operative interference could not well be undertaken. In each instance the operation probably prolonged life. The operation is performed under desperate circumstances, and the fact that it does not produce a permanent cure in every case in no way militates against its employment.

63. **New Operation for Hernia of Pelvic Floor.**—After two complete attempts to correct a complete hernia of the pelvic floor, Crile finally succeeded by performing an operation which he describes as follows: With the patient in the Trendelenburg posture, a median incision of good length was made; approximately one-fourth of the entire abdominal contents were withdrawn from the hernial sac, the pelvic floor steadied and the hernia reduced. The bladder was found well down in this cavity and totally prolapsed. An anteroposterior incision was made across the middle of the floor of the pelvis, dividing the vagina into two lateral halves. The vaginal mucous membrane of the part to be brought through the abdominal incision was removed. The bladder was separated from the vagina for some distance downward. It was then found that the vagina and the floor of the pelvis had been so stretched that they could easily be brought out through the abdominal wound beyond the surface of the skin. After making an incision through the abdominal fascia 4 cm. from the median line on each side, the fibers of the recti were separated and the peritoneum perforated. Each half of the split vagina with the attached uterosacral and uteropelvic ligaments and all the other structures of the floor of the pelvis, together with the round and broad ligaments, were drawn out through these openings on each side of the median incision. While the parts are well up in place so that the top of the incised vagina presented closely against the under surface of the peritoneum, the latter was sutured in this position with plain catgut. The original peritoneal incision, the muscle and the external fascia were then closed, the latter by continuous sutures of chromicized gut, after which the freed ends of the vagina and pelvic floor, which had been drawn up through the lateral openings in the peritoneum, recti and fascia, were united in the middle line by means of chromicized gut. The skin was then closed. The patient made a good recovery from the operation and was discharged in three and one-half weeks. For some time after the operation the patient felt a sensation of dragging on the wound and experienced some pain. This passed away after several months. She has been doing her usual work, and at the present time, more than three years after the operation, there has been no recurrence of the hernia. Crile says the indication for this operation exists only in the cases of complete hernia (procidentia). In the minor degrees of prolapse it would be quite impossible to carry out this technic for want of sufficient length of ligaments and of vagina to reach to the external fascia.

68 Case of Acute Malignant Pemphigus (P. Vegetans), with Autopsy Report. O. S. Ormsby, and P. Bassoe, Chicago.
69 Clinical and Microscopic Reports of Dermatologic Cases. L. E. Schmidt, Chicago.

67. **Varicella Accompanying Herpes Zoster.**—Corlett reports 4 cases. The first patient was a woman, aged about 48, who came to see him because of herpes zoster involving the lateral surface of the neck, thence passing over the shoulder and down the arm and the trunk in the vicinity of the left mamma. On the back, chest and extremities were lesions resembling those of varicella. The only conclusion obtainable was that the patient had an attack of herpes zoster occurring simultaneously with varicella. The second patient was a man, aged 44, who had a herpes zoster frontalis with a typical varicella eruption on the chest, arms, legs and back. The third case, a man aged 40, corresponded to the first two. The fourth case, a man, aged 70, had herpes zoster in the area supplied by the second lumbar nerve and a varicella eruption on the trunk and forehead.

71. **Typhoid with Complications.**—The case reported by Friedrich is interesting because of the many and serious complications which developed. The fever was unusually irregular, the temperature often being 103 and 104 for two days, then dropping to normal, again rising, and again falling to normal and even subnormal, continuing thus an erratic course for three weeks, and then, without apparent cause, rapidly rising again. Vomiting was very persistent, the ejected matter containing mucus and bile. The abdominal symptoms were greatly exaggerated. The eruption was very extensive, petechiæ of immense size and varying in color from bright red to dark brown, and extending from the abdomen over the chest and back. A severe diarrhea, alternating with dysentery, developed, and there were many profuse hemorrhages. Jaundice was marked. About the thirtieth day of the disease an acute lobar pneumonia developed. Nephritis, accompanied by cystitis, was one of the most persistent complications. Symptoms of uremia supervened, and marked general convulsions were noted. Suppression of urine, alternating with re-

tention, became most aggravating. The nervous symptoms were severe. Besides convulsions there were delirium and coma, subsultus tendinum, carphology, a marked ataxic condition, and tenderness and hyperesthesia along the spine. There was also extreme deafness. The gastric complications were so severe that no food could be taken by mouth. Herpes labialis was very marked and a facial erysipelas became most annoying. Perforation of the bowel occurred at the end of the third month, and a few days afterward the patient collapsed and died.

84. **New Head Support in High Pott's Disease.**—The brace dtscribed by Eikenbarry is made of celluloid and stockinet, and is so constructed that it accurately fits the body, the neck and the posterior and lateral aspects of the head. By means of the webbing band passing around the forehead the head and neck are immobilized. There are no adjustments to make, nothing to get out of shape and destroy the fit and thus the effectiveness. The brace has also the advantage of being very light, the ordinary jacket weighing not more than a pound. If used for a dorsal or lumbar Pott's, where no headpiece is needed, the weight would not exceed ten or twelve ounces. The jacket is considerably less than a quarter of an inch thick, and is so strong that it easily bears a weight of 150 pounds. An accurately fitting plaster jacket is applied, including the neck and head. This is removed in the usual way by cutting down the front. From this mold a plaster model is cast. The plaster model is shellaced so as to prevent crumbling of the plaster. Over the model successive layers of the stockinet are drawn, each layer in turn being given a rather thick coat of the celluloid solution. Nine or ten layers are quite sufficient. None of the solution should penetrate to the inner side of the inner layer, or to the outer side of the outer layer, so as to have a perfectly smooth jacket inside and out. After applying the last layer, allow the model to set for twenty-four hours, and then trim the jacket before removing from the cast. Cut down the front in the usual way, bind the edges with chamois or cloth, and place a double row of hooks in front. The celluloid solution is made by dissolving chips of celluloid in acetone, about twenty-four hours being required for solution. The solution should have the consistency of cream.

89. **Complicated Heart Case.**—Rees' patient gave a history of rheumatism which was followed by the development of aortic stenosis and regurgitation, a relative mitral insufficiency and sacular aneurism of the arch and descending portion of the aorta. The arch was very much hypertrophied, the apex being located in the sixth interspace in the midaxillary line. The pulsation in the vessels of the neck was prominent and jerky. A pronounced, continuous thrill was felt extending from the first to the fifth rib on the left of the sternum, and also along the right upper portion of the sternum in the suprasternal notch and in the vessels of the neck. The general health of the patient was good.

7. Fixation of Testes to Thigh.—Keetley reports on a series of twenty-five patients operated on for undescended testes, the plan of keeping down the testicle after operation being fixation to the thigh, a method devised by the author in 1894. The main incision is made over the inguinal canal and the external ring. Two other skin incisions are made in most cases, one about one and a quarter inches long at the bottom of the scrotum, and another of the same size in the upper and inner part of the thigh adjacent to the scrotal incision. Before cutting the scrotal incision a bed should be made with the finger in the scrotum to receive the testicle and the scrotal incision should divide all the structures down to this bed. Something, either a blunt instrument or a piece of gauze, should be passed through this scrotal aperture immediately, or its different layers will cease to be opposite one another. The thigh incision should expose the fascia lata. The testicles and the cord having been thoroughly freed from everything but the musculo-fibrous bands forming the gubernaculum, which are generally attached to the pillars of the external ring, especially the internal pillar, the gubernaculum is divided as far away as possible from the testicle. A pair of forceps is then passed from below upwards through the hole in the scrotum and the gubernaculum is seized by it and pulled right through the scrotum till it can be seen through the hole in the skin of the scrotum. At the same time the tunica vaginalis should also be pulled down into the scrotum, though it is not absolutely necessary to keep the testicle in its serous bag. The posterior borders of the apertures in the skin of the scrotum and thigh are next united by a continuous silkworm-gut suture left long at both ends. Now the gubernaculum testis is sutured with strong catgut to the fascia lata of the thigh; and, lastly, the original silkworm-gut suture is used to complete the union of the skin apertures in the scrotum and thigh to one another. The patient is sent to bed with his hip flexed, but soon straightens it out himself, thus gradually lengthening a short cord. For a dressing Keetley uses iodoform gauze wrung out in 1 in 2,000 bichlorid solution, the gauze being passed behind the scrotum as well as in front, and over the gauze, salicylate wool. The testicle is left attached to the thigh for five months. The operation is free from complications. The testicle remains permanently near the root of the scrotum.

10. Tuberculous Disease of Cecum.—Stoney's patient complained chiefly of pain in the left hip, most marked at night, which traveled down the back of the leg to the ankle. She also had some pains in the stomach, palpitation of the heart, giddiness, headache, and general weakness. Examination showed the hip to be normal, but there was much pain and tenderness on pressure over the spines of the first and second lumbar vertebræ. A large, somewhat irregular tumor was felt in the right iliac fossa. The abdomen was opened, and the cecum removed. Its walls were enormously thickened; the ileocecal valve was closed, and the opening of the appendix was reduced to a minute hole. Microscopic examination of the tissue disclosed a typical tuberculosis.

11. Rapid Estimation of Sugar in Urine.—Williamson describes a modification of Gerrard's method. The estimation can be made in a few minutes; only a small amount of urine is required, and the results are sufficiently accurate for most clinical work. The only apparatus required are a test-tube of ordinary size, a small narrow burette and a spirit lamp.

13. Dysentery in Prisons.—Fearnside reviews the medical history of the prisons in the Madras presidency since 1867 with reference to the rôle dysentery played in the vital statistics. He concludes as follows: 1. Dysentery in the Madras prisons has accounted for the majority of deaths during the past forty years. 2. Many diseases reported as debility, anasarca, etc., and now not recognized as such, were in reality dysentery. 3. Scarcity of food and bad food predispose to dysentery both outside and inside the jails of the presidency. 4. Impure water has a similar effect, and the obsolete arrangement of the hand delivery of water should be abolished at an early date, taps and shower-baths being introduced. 5. Dysentery being an infectious disease should be treated in an extramural hospital specially built for the purpose. 6. The abolition of the association wards and the introduction of the cellular system is most essential and is an excellent preventive for the spread of any such disease since the person attacked is practicallly segregated, whereas in a barrack this is not so. 7. The abolition of mud banks and the introduction of plank beds, the former being septic and insanitary. 8. Patients who have suffered from dysentery should be kept separate for some time during convalescence as they are dangerous to the community within the prison. 9. The free use of anthelmintics in the treatment of prison dysentery since so many of these individuals harbor internal parasites. 10. Special care, during treatment, should be taken to prevent dysenteric patients receiving food other than that prescribed.

16. **Treatment of Dysentery.**—Matthews washes and dries in the sun the roots and lowest trunks of the ordinary garden geranium. Then he boils one quarter pound in a pint of milk for one hour, adding milk from time to time to make up the pint. This infusion is then strained through fine muslin, and two ounces are given every two hours until the disease is cured, which is usually in from two to six days. Treatment by this drug has several advantages: 1. In most cases, if not prolonged beyond five or six days, it is not necessary to give any other food, the dosage used giving the patient 1¼ pints of milk daily. 2. It is not nauseating; as a rule quickly relieves the nausea and pain in the abdomen, nor is it debilitating. 3. Its action seems to be entirely specific.

21. **Id.**—Deb relates his experience with *Ixora coccnia* in the treatment of acute bloody dysentery. The method of preparation employed was grinding the fresh root on a currystone with a small piece of long pepper and mixing the pulp so produced with water, or by preparing a tincture of 4 ozs. of the root to a pint of proof spirit. The dose of the root was from 10 to 30 grs. two or three times a day and the dose of the tincture from ʒi to ʒiss thrice a day with a few drops of tincture of opium according to the age and constitution and requirements of the patients. Tincture of ixora acts well with or without opium. Tincture of opium or long pepper adds to its efficacy, does no harm and acts promptly. According to Deb, it is not laxative or purgative, nor has it any ecbolic action like ipecac. It is suitable in all cases, especially in the hemorrhagic variety. The effect is noticeable within twenty-four hours after administration of the drug.

24. **Treatment of Hyperacidity.**—Albu recognizes the following forms of hyperchlorhydria: 1, A purely nervous disturbance of secretion; 2, that accompanying chlorosis; 3, an early stage of peptic ulcer; 4, the expression of a chronic hyperplastic gastritis. The treatment must be primarily dietetic and must not only exclude acid foods, gravies, spices, alcoholics and other irritating materials, but must also provide a detailed diet. The author recommends a vegetable diet in place of the alubuminous diet long considered indispensable, because although albumin combines with HCl, it also increases its secretion. The food must be well cooked and finely divided, if necessary, by putting through a sieve. Starchy foods are well tolerated if made of the finest meal from which the gluten has been practically removed. Fine wheat bread is to be preferred. While coarser vegetables are excluded, fine vegetable purées such as spinach or cauliflower are harmless. Albuminous foods may be taken with the exception of some fatty forms such as goose, pork, bacon, eel, herring, etc. The only fats of value are unsalted butter, milk and cream, and egg fat, because they are so easily emulsified. On account of the favorable action of fat he recommends from 1 to 2 tablespoonfuls of olive oil taken from one to two hours after the principal meals. Cane sugar is well borne by only a few of the patients. Milk, cream, cocoa, chocolate or weak tea may be given if they seem to agree with individuals. Small meals at frequent intervals are best in order to combine quickly the excessive secretion of acid. It is also advisable to eat a little before retiring or on waking, to prevent faintness. In stubborn cases stomach lavage is the best treatment, especially late in the evening, about three hours after the last meal, so as to give an undisturbed night's rest, or, if this is impracticable, in the morning on an empty stomach. The author recommends lavage with water holding in suspension a mixture of magnesium and sodium bicarbonate. To restrain the production of acid he recommends a combination of alkali and belladonna. For constipation he uses vegetable diet, oil, enemata, and an occasional cathartic. Hypersecretion, he states, is usually a complication of gastrectasia, atony, ulcer, hyperchlorhydria, or an independent secretion continuous in Reichmann's disease or intermittent, dependent on disease of the central nervous system. The treatment should depend on the underlying affection. Liquids should be limited in amount. Food should be administered in the form of mush, gruel or purée in small and frequent meals. The milk may be boiled down to half its volume in order to get rid of the useless water, which is even harmful on account of its weight. The choice of nourishment should be exactly like that in hyperchlorhydria, since the latter is always an accompaniment of hypersecretion. Lavage late in the evening serves to remove the excess of secretion and care should be taken to remove all of the fluid introduced.

26. **Free Formaldehyd in the Blood After Internal Use.**—Rosenberg presents experimental evidence that free formaldehyd may exist in the blood to the extent of 0.0775 per cent. after the administration of tablet containing the drug in combination with milk sugar. It is excreted in the urine and in the milk. This quantity, he believes, can act as a disinfectant.

27. **Astasia-Abasia.**—Hammer treats hysterical astasia-abasia (inability to stand or walk) by seclusion in the hospital ward by means of screens that prevent the patient from seeing his neighbors, although he can hear conversation and know what is going on. This fact intensifies the patient's desire to get well and facilitates the other treatment. Suggestion is best carried out in the waking state, as experience has shown this to be more effective than hypnosis. The ex-

ercises are used to suggest a strengthening of the limbs, especially the feet, and emphasis is laid on every sign of improvement. A generous diet, largely milk, is administered. By this method five patients were permanently cured.

29. **Tuberculosis of Mesenteric Glands in Children.**—Hecht relies for diagnosis of tuberculosis of the mesenteric glands on the history, on the tenderness of the abdomen, on the abdominal pains present on both sides, and on the occasional presence of a palpable tumor or tumors. The feces often show the presence of mucus, blood and tubercle bacilli in cases in which there is no diarrhea. The prognosis is by no means hopeless, but treatment must be prolonged, lasting months or even years. If practicable, sea bathing is advisable.

30. **Varicose Ulcers.**—Loele advises the ambulant treatment of leg ulcers because the patients, who usually belong to the lower classes, will not lie abed or enter a hospital while the ulcer is of a size to be easily curable. He uses a modification of Jessner's method, which consists of cleansing the ulcer and its neighborhood with benzine, dusting it with an antiseptic powder and covering it with oiled silk. A roller bandage of cotton 20 cm. wide is then applied over the whole lower third of the leg, including the ankle and the ulcer. Over this an elastic bandage is carefully applied. If applied with sufficient firmness a new dressing need not be applied oftener than once a week. With this treatment an ulcer the size of a dollar should heal in about six weeks.

31. **Treatment of Erysipelas with Credé's Ointment.**—In cases of erysipelas at points where compression by adhesive plaster or collodion can not be applied, as on the neck or chest, Born recommends applying Credé's ointment around the affected area, rubbing the ointment into the tissues with the fingers. The rubbing must be continued on the same part of the skin for thirty minutes, and must be carefully done to avoid hurting the patient. It is repeated on three successive days, and when properly done has been uniformly successful in limiting the spread of the disease. It acts by introducing into the subcutaneous connective tissue enough silver to act as a bactericide in this encircling zone.

32. **External Temperature in Diabetes.**—According to Lüthje's experiments, external cold increases the decomposition of albumin and excretion of sugar in diabetic dogs, with retention of nitrogen. The external temperature should be more carefully regarded in experimental research in diabetes, and failure to do this probably explains some of the discrepancies in the published results. Observations on 4 diabetics from a month to six weeks showed analogous fluctuations in the excretion of sugar, the amount increasing at low temperatures (15 C.) and diminishing at high temperatures. The increase of tolerance thus obtained may be of the greatest practical importance.

33. **Alternating Currents in Treatment of Heart Affections.**—Laqueur has experimented to determine the action of alternating currents (sinusoidal) on the size of the heart, with the result that, with the exception of a case of neurasthenia of the heart complicated with slight dilatation, alternating currents brought about no immediate change in the size of the heart. Permanent diminution in size occurs only occasionally, when dilatation is caused by relaxation, but not when compensating dilatation in case of valvular defect is combined with hypertrophy. Increase of blood pressure is usual but not constant. In contrast to other authors, Laqueur does not consider alternating currents necessarily contraindicated in heart diseases with increased blood pressure. Slowing of the pulse is still less constant, and is probably attributable to the effect of rest. Subjective symptoms, however, are often much improved. Relief of dyspepsia, increase of appetite and better sleep are noticed. The author agrees with Lippert that the chief action of sinusoidal currents consists in the increase of blood pressure, often accompanied by diminution of frequency of the pulse in the energetic stimulation of metabolism, promotion of sleep and increase of the motor energy of the heart and of the other muscles of the body. The indications for this treatment are weakness with dilatation of the heart caused by relaxation of the heart muscle, fatty heart, idiopathic hypertrophy of the heart, and also incipient disease of the myocardium and incipient arteriosclerosis. The author does not agree with Zimmermann. In pronounced arteriosclerosis with increased blood pressure the application of this current is contraindicated as well as in aneurism. For these conditions carbonated baths are preferable. General neurasthenics are not improved, but cases of neurasthenic cardiac weakness without marked general symptoms do well. It is better than Faradism because of its greater uniformity of current. The author prefers the full bath to local applications, but describes an apparatus for local application which he has found to exert a good influence on the heart. The action of alternating currents is twofold: On the one hand the current causes an irritation of the sensory nerves of the skin and by reflex action elicits better heart innervation (increase of blood pressure, more powerful contraction of the heart, and slowing of the pulse). On the other hand, the peculiar muscular contractions which the current elicits exert a certain favorable influence on the circulation. The alternating current baths fail, however, to dilate the blood vessels like the carbonated baths. A current bath is always more of a heart-stimulating than a heart-sparing procedure.

35. **Spastic Constipation.**—Albu emphasizes the fact that the treatment of spastic constipation must be based on an exact knowledge of the character of the affection and of the condition of the patient. As spasm is developed on an atonic basis, everything favoring its development must be avoided, especially massage and cathartics. Treatment must be directed to allaying irritation and should include warm, hot or carbonated baths, hot abdominal compresses, warm oil enemata (250 c.cm. every evening), atropin or belladonna suppositories, and a generous diet, largely vegetable, free from all substances (hulls, seeds, etc.) that might irritate the intestine, prepared so as to be capable of very fine subdivision (bread from very fine wheat flour, vegetables in form of purée, cooked fruits, soups, milk, etc.). Alcohol, spices, cabbage, cucumbers, lettuce, cheese, etc., should be avoided. A further important measure is the daily introduction of well oiled bougies for from 5 to 10 cm. into the rectum, allowing them to remain from ten to fifteen minutes. Rest in bed is to be recommended only in case of much reduced patients, as it tends to increase the atony of the bowel. A Weir Mitchell cure in some cases, however, gives remarkably good results.

36. **The Bicycle in Treatment of Sexual Neurasthenia.**—Fürbinger recommends the bicycle as a healthful exercise in the open air which insures good circulation and sufficient use of the muscles without exhaustion, and rests the brain and nervous system while using the organs of special sense. In sexual neurasthenia impotentce is likely to be favorably influenced by the general tonic influence of the sport. Exceptions occur which must be individually treated. Seminal losses are variably affected. A large number of patients are made worse, and these should avoid the wheel. Others are favorably influenced, and in the majority of cases no fear need be entertained that cyclotherapy will originate seminal losses. The prescription of this form of exercise should be in the hands of a physician who is a bicycler himself, and can give suitable advice as to the length of ride, kind of saddle, etc.
